FuxCP : A Validated Constraint Programming Formalization of Fux Four-Voice Counterpoint

Author: **Tom Lai**
Supervisor: **Peter Van Roy**
Readers: **Karim Haddad, Hélène Verhaeghe**
Academic year 2024–2025
Master [120] in Computer Science

Abstract

This thesis takes over the constraint-programming formalization of Fux's musical theory developed in prior work and consolidates, clarifies, and validates the rule system for Fuxian counterpoint. The model distinguishes hard rules (stylistic necessities) from soft preferences (graded tendencies) and adopts a figure-driven validation methodology based on Minimal Unsatisfiable Subsets (MUS) to diagnose and resolve tensions between the formalism, Fux's examples, and auxiliary sources. Validation proceeds along four complementary axes: (i) consistency with implicit theoretical knowledge and practical pedagogy; (ii) verification against worked examples from Gradus ad Parnassum using MUS to isolate minimal conflicts; (iii) cross-checking with the explicit formulations in the Traité de Contrepoint by Noël Gallon and Marcel Bitsch; and (iv) systematic correction of formulation inconsistencies and implementation errors inherited from previous iterations.

On the engineering side, the thesis extends and corrects the Gecode-based solver, introduces a modular activation/deactivation mechanism that enables controlled experimentation with subsets of rules, and integrates MUS diagnostics directly into the testing pipeline. Several rules are re-cast as soft constraints to encode stylistic latitude without sacrificing correctness. A unified, documented constraint library and reproducible test harness (including species/voice-count figure tests) provide a coherent, maintainable framework for future research and extensions.

Together, these contributions deliver a clearer and more faithful executable theory of species counterpoint: a consolidated catalogue of general and species-specific constraints with explicit domains of application; an implementation that explains failures at rule level via MUS; and a validated workflow that reproduces Fux's figures where supported and pinpoints precisely where the model must be refined or extended.

Acknowledgments

I am deeply grateful to my supervisor, **Peter Van Roy**, for his unwavering enthusiasm for this project, his availability, and his guidance that consistently steered me in the right direction. Thanks to him, I had the opportunity to meet **Hélène Verhaeghe** and **Karim Haddad**.

My sincere thanks go to **Hélène Verhaeghe** (École polytechnique de Louvain) for taking the time to discuss the project with us and for her crucial advice to employ *Minimal Unsatisfiable Subsets (MUSes)* to test the program against Fux's examples.

I also extend my gratitude to **Karim Haddad**, Doctor in Musicology and specialist in counterpoint, for sharing his expertise, for the many meetings we held, and for his remarkably swift and thoughtful email responses.

I warmly thank the previous contributors to this project—**Damien Sprockeels**, **Thibault Wafflard**, **Anton Lamotte**, **Luc Cleenewerk**, and **Diego de Patoul**—for the quality and rigor of their work, which laid the foundations for the present thesis.

Finally, I am indebted to my **family and friends** for their unfailing support and encouragement throughout this journey.

Contents

Chapter 1

Introduction

1.1 State of the Art in Musical Automation

From the earliest days of computational music, computer-assisted composition has balanced the intuitive with the formal rule. On one hand, machine learning embraces the organic flux of musical expression; on the other, constraint programming offers the precision of codified tradition. Together, these two paradigms define the breadth of contemporary musical automation—from impressionistic generative systems to rigorously rule-based solvers.

Machine Learning and Music

In the realm of machine learning, music becomes data—melodies, harmonies, and expressive timings encoded as patterns to be learned, mimicked, and transformed. Deep learning models now address composition across multiple levels: score generation, performance nuances, and even audio synthesis. A comprehensive survey highlights how these tiers are interwoven through evolving architectures, diverse datasets, and evaluation methods—and also shines a light on the persistent challenges of creativity, structure, and control.[3]

Projects like AIVA, an acclaimed AI composer trained on the masters of Western art music, illustrate how deep architectures and reinforcement learning yield expressive, stylistically rich compositions.[1]

Other systems—from Google's Magenta[11] (which powers interactive tools like AI Duet[10]) to Sony's Flow Machines[16]—highlight both the playful and practical potential of AI in composing music, while prompting ongoing reflection on originality and collaboration.

Yet the poetry of machine-generated music is not without unease. Critics caution that such systems often yield stereotyped patterns, constrained by their training data, and may lack the capacity for expressive deviation or meaningful invention. Deep learning models also struggle with direct user control over tonality, form, or expressive intent—a limitation particularly relevant in counterpoint, where rule shaping is paramount.

Constraint Programming and Music

In contrast, constraint programming (CP) offers a more disciplined artistry—a way of embedding music theory as solvable logic. You define the rules; the computer ensures compliance. The appeal lies in encoding precise stylistic norms leveraging declarative constraints and powerful solver frameworks.

Indeed, counterpoint—especially in the style of Fux—lends itself well to such formalism. Its strict rules, once translated into constraints, can be solved efficiently to generate valid and stylistically faithful musical lines. Early work like Ebcioglu's florid counterpoint system enumerated dozens of constraints to produce conservatory-level examples.[6]

Schottstaedt later modeled all five species of Fuxian counterpoint for up to six voices, even adding "penalty" values to compensate rules flexibility.[14]

Other musicians and researchers explored polyphonic textures ranging from atonal to Ligeti-like structures, further confirming the adaptability of CP in composition.

However, constraint-based approaches have their own limitations. They require exhaustive rules formalization, often sacrificing nuance or expressive exceptions that a human composer might apply "by ear." Moreover, such systems may lack fluid interactivity or the capacity to learn new stylistic variations.

1.2 FuxCP Context

FuxCP is a computer-aided composition tool that formalizes the counterpoint pedagogy of Johann Joseph Fux's *Gradus ad Parnassum* as a set of mathematical rules and solves them with a constraint solver to produce musically valid counterpoint. It was initiated as a collaboration between UCLouvain and IRCAM and conceived to assist composers—especially those without programming expertise—by turning species-specific rules into constraints the computer can enforce and explore systematically. In its most recent form, FuxCP comprises a rigorously specified rule base and an implementation over the Gecode[15] solver that can generate contrapuntal lines consistent with the relevant species and stylistic preferences.

Constraint programming (CP) is an appropriate foundation for this project because it offers transparency and control: rules are explicit, traceable constraints; preferences can be encoded as soft constraints or costs; and solutions can be inspected and steered rather than inferred opaquely from data. Prior work in FuxCP repeatedly emphasized these advantages over black-box generative approaches, arguing that CP "understands" and enforces the theory while still leaving room to shape musical outcomes. In practice, the framework separates hard stylistic rules from adjustable preferences, which is critical for balancing correctness with musical nuance.

Historically, the project grew alongside IRCAM's OpenMusic[12]. OpenMusic (OM) is IRCAM's visual programming environment for computer-assisted composition, built on Common Lisp. On this foundation, the project evolved through four theses. In 2022, Damien Sprockeels developed Melodizer, estab-

lishing the GiL bridge between OM (Lisp) and Gecode[15] (C++) and demonstrating interactive constraint-based composition in which mandatory rules can be combined with optional preferences[17]. In 2023, Thibault Wafflard introduced FuxCP proper for two-voice species, mapping Fux's rules to constraints and exposing them in OM for composer-facing use[18]. In 2024, Anton Lamotte generalized the model to three voices, formalizing interactions with the lowest voice and introducing strata while clarifying the role of soft constraints to preserve stylistic nuance[13]. Later in 2024, Luc Cleenewerk and Diego de Patoul unified the accumulated rule sets, extended FuxCP to four voices, and migrated the implementation to an object-oriented C++ codebase on Gecode[5].

OpenMusic is no longer used in the current line of work. FuxCP is now maintained as a standalone C++ library with a stable API, and a native C++ graphical interface for the project is being developed in a separate master's thesis. This decoupling keeps the solver transparent and testable while preparing the project for broader integration.

1.3 Contribution

This section presents the main outcomes of the work and how they advance FuxCP from both a theoretical and an engineering standpoint. On the conceptual side, the thesis consolidates, clarifies, and validates the formal rule system for Fuxian counterpoint—separating hard rules from soft stylistic preferences and using MUS-based analysis to resolve tensions between the model, Fux's examples, and auxiliary sources. On the implementation side, it extends and corrects the Gecode-based solver, introduces modular mechanisms for activating subsets of constraints and MUS diagnostics, and unifies the rule library and documentation into a coherent, testable framework. The contributions are summarised below under two complementary headings: conceptual and implementation.

Conceptual contributions

- Validation and correction of the formal model of Fuxian counterpoint
  - Validation of the mathematical definitions of the rules and their formulation as constraints.
  - Validation performed in four complementary directions:
    * Comparison with implicit theoretical knowledge of counterpoint practice.
    * Verification against musical examples in *Gradus ad Parnassum* by Johann Joseph Fux[8] [4], using Minimal Unsatisfiable Subset (MUS) analysis.
    * Cross-checking with the 20th-century treatise of Noël Gallon and Marcel Bitsch[9].

    - ∗ Identification and correction of formulation errors and inconsistencies in previous work.

- Refinement of the theoretical framework by distinguishing between rules, preferences, and stylistic constraints, thus providing a more flexible interpretation of the counterpoint tradition.
- Introduction of MUS techniques into the analysis of musical rules, demonstrating their applicability to music theory as a method for detecting conflicts and implicit assumptions.

Implementation contributions

- Extension and correction of the constraint-based model in Gecode[15]
    - Correction of erroneous rule implementations inherited from previous versions.
    - Transformation of certain rules into soft constraints or preferences, allowing for a graded handling of stylistic deviations.
- Integration of MUS analysis into the solver framework, enabling the systematic detection of inconsistent rule sets in practical musical examples.
- Development of a modular activation/deactivation mechanism for constraints, allowing controlled experimentation with subsets of rules and precise reproduction of Fux's musical figures.
- Testing and validation through computational experiments, reproducing Fux's examples (when compatible with the solver's scope) and identifying cases where the model had to be refined or extended.
- Documentation and unification of the constraint library, providing a coherent basis for future research and extensions of the system.

Roadmap

- **Chapter 2 — Background.** Fixes the terminology and scope that the formal model presupposes, positions the work within the historical and theoretical lineage of species counterpoint and outlines the roles of Fux and of Gallon–Bitsch.
- **Chapter 3 — Concepts, Variables, and Data Structures.** Introduces the computational abstractions (voices, parts, strata) and the core arrays used throughout the model, together with the notational conventions and preference machinery that support subsequent formalization.
- **Chapter 4 — Program Architecture.** Details the software design: constraint posting and search pipeline, class hierarchy and responsibilities, and the extension points that enable controlled experimentation and reproducibility.

- **Chapter 5 — Model Validation.** Presents the validation methodology—unit tests, figure-driven evaluation, and MUS-based analysis—together with the activation/deactivation mechanism for constraints and the control loop used to isolate inconsistencies.
- **Chapter 6 — Rule-by-Rule Analysis.** Conducts a systematic audit of the rule set, discussing delayed notes and strata, undocumented or derogated cases, and providing reasoned corrections grounded in both musical practice and solver evidence.
- **Chapter 7 — Full Validated Model of Fux Counterpoint.** Assembles the validated rule catalogue—general and species-specific, including fifth-species rhythmic logic—states their domains of application, and summarizes the rules scope in compact tables.
- **Chapter 8 — Limitations and Future Work.** Identifies current boundaries of the approach and outlines concrete avenues for extension, from rhythmic and ornamental coverage to multi-voice interactions and broader stylistic variants.
- **Chapter 9 — Conclusion.** Synthesizes the main results and contributions, and sketches how the framework may support future research in computational counterpoint.

Chapter 2

Background

This chapter fixes the musical and historical groundwork that the formal model presupposes. It clarifies the terminology used throughout the thesis, recalls the essentials of species counterpoint, and situates our reading of the treatises on which the model relies.

2.1 Music Concepts

This section provides a brief overview of the key terms, ensuring consistency of usage and avoiding ambiguity in the chapters that follow.

Staff A set of five parallel horizontal lines and the four spaces between them, used in Western music notation to indicate pitch and rhythm. The position of a symbol on the staff, in combination with a clef, determines the pitch it represents.

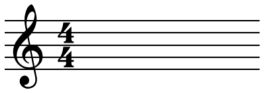

Figure 2.1: Staff with a treble clef, an empty key signature and a 4/4 time signature.

Note A symbol in musical notation indicating both a specific pitch and its duration. The visual form of the note (filled or unfilled head, stem, flags) represents its rhythmic value, while its vertical position on the staff specifies its pitch.

Beat The basic unit of time in music, representing the regular pulse that underlies a piece. Beats are grouped into measures according to the time signature.

Measure A segment of time in musical notation, defined by a set number of beats as indicated by the time signature, and separated from adjacent measures by bar lines. Measures provide a structural framework for rhythm and phrasing. In a common $\frac{4}{4}$ time signature, a measure is made up of four beats.

Pitch The perceived highness or lowness of a sound, determined primarily by the frequency of its vibration, measured in hertz (Hz).

MIDI Acronym for Musical Instrument Digital Interface. A communication protocol for electronic musical instruments and computers. In notation, MIDI pitch values are integers from 0 (C–1) to 127 (G9), each corresponding to a specific note frequency.

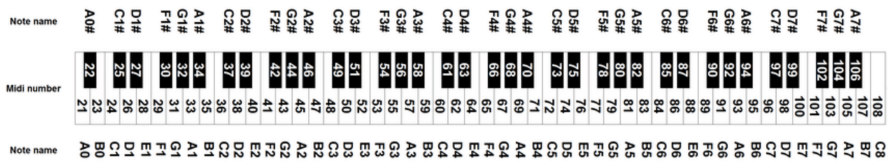

Figure 2.2: classical keyboard note names and MIDI values

Intervals The pitch distance between two notes, measured in semitones or by their ordinal name (e.g., minor third, perfect fifth). Intervals can be melodic (successive notes) or harmonic (simultaneous notes).

Interval	Unison/Octave	Second		Third		Fourth	Tritone	Fifth	Sixth		Seventh	
Type	Perfect	Minor	Major	Minor	Major	Perfect	$\sharp 4^{th}$ / $\flat 5^{th}$	Perfect	Minor	Major	Minor	Major
Value	0	1	2	3	4	5	6	7	8	9	10	11

Figure 2.3: MIDI values of the intervals over an octave range

Semitone The smallest standard interval in Western music, equal to one twelfth of an octave. It corresponds to the distance in pitch between two consecutive keys on a piano keyboard, whether white-to-black or white-to-white where no black key intervenes (e.g., E to F, or B to C).

Step A melodic movement of either one semitone (half step) or two semitones (whole step) between consecutive notes in a scale.

Leap A melodic movement larger than a step, typically defined as an interval of a third or more between consecutive notes.

Types of notes Categories of note values defined by their relative duration. Common types include whole notes (longest standard duration), half notes, quarter notes, eighth notes, and sixteenth notes, each typically half the dura-

tion of the previous.

- **A whole note** represents a long duration of sound and lasts four beats.
- **A half note** represents a medium duration of sound and lasts two beats.
- **A quarter note** represents a short duration of sound and lasts one beat.

Figure 2.4: The 3 main types of notes used in the counterpoint.

Syncopation A rhythmic device in which emphasis is placed on normally weak beats or off-beats, often by sustaining a note across a strong beat or accenting unexpected positions in the measure. In the English translation of *Gradus ad Parnassum* by Alfred Mann[8], this practice is also referred to as a "ligature."

Delayed Note In counterpoint, a delayed note (also called a suspension) is a note that is held over from a previous harmony, creating a temporary dissonance on the thesis (downbeat) before resolving stepwise—usually downward—into a consonant interval on the following arsis (upbeat).

Tonic The central pitch of a scale, serving as its tonal "home" and the point of resolution for melodic and harmonic progressions.

Scale An ordered sequence of pitches spanning an octave, constructed according to a specific pattern of intervals (e.g., major, minor, modal).

Key A tonal framework defined by a tonic and a scale type (e.g., C major, A minor), determining the set of diatonic pitches used in a piece.

Mode A type of scale distinguished by its pattern of whole and half steps relative to the tonic. In Western music, common modes include Ionian (major), Dorian, Phrygian, Lydian, Mixolydian, Aeolian (natural minor), and Locrian.

Diatonic Pertaining to a set of seven pitches forming a major or minor scale within a given key, excluding chromatic alterations.

Chromatic Pertaining to the complete set of twelve pitches in the octave, including both the diatonic pitches and their altered (sharp/flat) counterparts.

Borrowed note A pitch that lies outside the diatonic scale of the current key, typically borrowed from a parallel mode or key.

Degree The position of a note within a scale, numbered from 1 (the tonic) to 7. Degrees are typically indicated using Roman numerals for harmonic analysis (I–VII).

Joint degree In melodic motion, a note that is one scale degree away from another note within the same scale, producing a stepwise movement (either ascending or descending by a second). Joint degrees correspond to motion by step.

Disjoint degree In melodic motion, a note that is more than one scale degree away from another note within the same scale, producing a leap. Disjoint degrees correspond to motion by intervals larger than a second.

Diminution In counterpoint, the process of filling the space of a larger interval (often a leap of a third) with one or more intermediate passing notes; more generally, the subdivision of a note into shorter rhythmic values.

Thesis or **Downbeat** The first and typically strongest beat of a measure.

Arsis or **Upbeat** A weaker beat or subdivision that leads into the next strong beat. With a common 4/4 time signature, the arsis is the third beat of any measure.

Ornaments Small, often quick embellishments added to a note or a short phrase to enrich the melody and make it more expressive.

2.2 Counterpoint

The counterpoint is a fundamental concept in the field of music theory and composition, representing a technique by which two or more independent melodic lines are combined to create a harmonious whole. The Counterpoint has had an enormous impact on classical Western music, particularly from the Renaissance and Baroque periods, and continues to influence contemporary musical practices.

2.3 *Gradus ad Parnassum* by Johann Joseph Fux

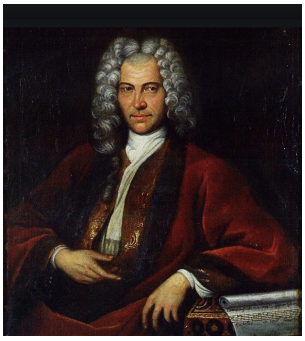

Figure 2.5: Portrait of Johann Joseph Fux by Jacob van Schuppen (around 1725).

Johann Joseph Fux, born in Hirtenfeld in 1660 and deceased in 1741, was an Austrian composer, music theorist, and pedagogue of the late Baroque era. He is best remembered for his treatise on counterpoint, *Gradus ad Parnassum*, first published in 1725 [7]. This work has become a cornerstone of Western music pedagogy, influencing generations of composers and theorists.

Gradus ad Parnassum is divided into two books. The first, now of mainly historical interest, reflects early eighteenth-century views on the mathematical foundations of music. The second is devoted to musical practice and addresses two central topics: counterpoint and fugue. Although Fux considered the fugue study of great importance, the counterpoint portion has achieved the most lasting influence and forms the basis for this thesis.

The treatise presents its ideas in the form of a dialogue between a master and a student, moving step by step through the method known as species counterpoint. This approach begins with simple note-against-note exercises and progressively introduces rhythmic variation, dissonance treatment, suspensions, and other contrapuntal devices. The dialogue form gives the work a pedagogical charm and historical authenticity but also means that rules are sometimes implied rather than systematically codified. Exceptions are occasionally given as examples rather than formal statements, and certain concepts rely on the shared assumptions of Fux's time, which can lead to interpretive ambiguities when attempting a strict formalization.

Figure 2.6: Cover of *Gradus ad Parnasum*

Influence and Legacy

The influence of *Gradus ad Parnassum* has been immense. Composers such as J.S. Bach, Mozart, Haydn, and Beethoven are known to have studied it closely—Haydn working through every lesson, and Beethoven creating a condensed abstract for personal reference. Its pedagogical structure and gradual learning process have made it a reference point for counterpoint teaching for nearly three centuries. Even today, it remains part of academic curricula worldwide.

From Historical Text to Computational Model

In the field of computer-assisted composition, Gradus ad Parnassum offers an unparalleled starting point for formalization due to its clear pedagogical progression and emphasis on rule-governed practice. However, the conversational style and occasional lack of explicitness mean that certain rules require interpretation before they can be translated into executable constraints.

2.4 *Traité de Contrepoint* by Noël-Gallon and Marcel Bitsch

While *Gradus ad Parnassum* stands as the historical and pedagogical foundation of the present work, its dialogical format—cast as an exchange between

master and student—inevitably introduces a degree of ambiguity. Certain rules are implied rather than explicitly stated, and exceptions are often embedded in anecdotal or contextual remarks. This stylistic choice reflects its eighteenth-century pedagogical context but can create interpretative uncertainty when attempting to formalize its principles into strict computational constraints.

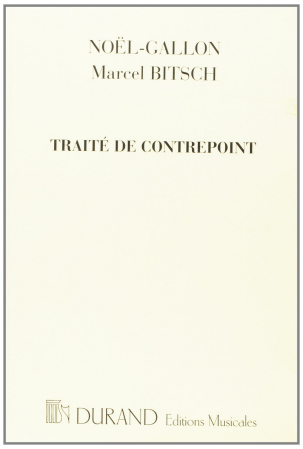

Figure 2.7: Cover of *Traité de Contrepoint*

By contrast, the *Traité de Contrepoint* [9] authored by Noël Gallon and later revised by Marcel Bitsch adopts a markedly different approach. First published in the 20th century within the framework of the French conservatoire tradition, this treatise is structured as a systematic and exhaustive exposition of counterpoint rules. Rather than unfolding as a narrative, it presents principles in direct, numbered form, each illustrated with precise musical examples. The organization is linear and explicit: rules are stated, justified, and exemplified without relying on implied context.

This difference in presentation is particularly valuable for a computational formalization such as FuxCP. Even though certain prescriptions in Gallon–Bitsch differ from those in Fux's text—reflecting both stylistic and pedagogical evolutions—the *Traité de Contrepoint* provides a clear reference point for resolving uncertainties. Where *Gradus ad Parnassum* might leave room for interpretation due to its conversational tone or its reliance on period-specific assumptions, Gallon and Bitsch's method offers unequivocal guidance, phrased in a way that directly lends itself to constraint definition.

For the purposes of the FuxCP project, the Gallon–Bitsch treatise serves not as a replacement for Fux, but as an authoritative auxiliary source. Its exhaustive structure ensures that rules are stated in their most operational form, enabling more precise encoding in constraint programming and reducing the risk of misinterpretation when translating historical principles into computational logic.

2.5 Forms and Configurations of Counterpoint

In the rest of this work, when we want to talk about the configuration of counterpoint, we will use the number of voices and the type of species used. It is therefore important to remember what this means.

Traditionally, as presented by Johann Joseph Fux in *Gradus ad Parnassum*, counterpoint may be written in two, three, or four voices. The simplest form involves a fixed melodic line, known as the *cantus firmus*, over which one or more counterpoint lines are composed. The *cantus firmus* (Latin for "fixed song") is a pre-existing melody, typically composed of long, evenly spaced notes and entirely consonant intervals. It serves as the structural backbone of

the composition, providing a stable framework against which the other voices are constructed.

In two-voice counterpoint, the interaction is limited to the cantus firmus and a single added voice, which allows a focused exploration of intervallic relations and melodic constraints. Three-voice counterpoint increases the complexity by requiring the composer to manage the interaction among all pairs of voices, while maintaining independence and avoiding forbidden motions such as parallel fifths. Four-voice counterpoint, commonly used in choral or harmonic contexts, demands full vertical coordination and careful distribution of motion, dissonance, and spacing.

First Species

In first species counterpoint, each note in the counterpoint line corresponds exactly to one note in the *cantus firmus*, creating a strict 1:1 rhythmic ratio.

Figure 2.8: Example of a four-voice counterpoint composition in the first species. [8, p.116 fig.172]

Second Species

Second species introduces rhythmic variation by allowing two counterpoint notes for every *cantus firmus* note (2:1 ratio).

Figure 2.9: Example of a four-voice counterpoint composition in the second species. [8, p.118 fig.176]

Third Species

Third species expands rhythmic density further, with four counterpoint notes per *cantus firmus* note (4:1 ratio).

Figure 2.10: Example of a four-voice counterpoint composition in the third species. [8, p.124 fig.184]

Fourth Species

Fourth species centers on the use of suspensions, where notes are tied over from weak beats to strong beats. The rhythmic structure typically involves half-note values tied across barlines. This species introduces controlled metrical tension and delayed resolution, enhancing expressive potential through syncopation.

Figure 2.11: Example of a four-voice counterpoint composition in the third species. [8, p.132 fig.196]

Fifth Species

Fifth species, also known as Florid counterpoint, integrates elements of all previous species, combining various rhythmic values, suspensions, and ornamental figures within a single line. It aims to emulate the natural flow of real polyphonic music while still adhering to contrapuntal rules. This species allows for the greatest expressive freedom and serves as a bridge to free composition.

Figure 2.12: Example of a four-voice counterpoint composition in the third species. [8, p.135 fig.201]

Species Mixture

In addition to the five traditional species, Fux also acknowledges the possibility of *mixed species* counterpoint, where different species are combined within a single composition. This type of writing allows for more realistic polyphonic textures and serves as a transitional step toward free composition.

The title of this section follows the terminology used in the *Traité de contrepoint* by Gallon and Bitsch, where the authors explicitly refer to this practice as "mélange des espèces" [9, p.16].

Figure 2.13: Example of a four-voice counterpoint with mixed-species. [8, p.137, fig.204]

We do not discuss this type of counterpoint in detail, since Fux himself treats it only briefly and provides a single illustrative example in his treatise which is shown above.

Chapter 3

Concepts, Variables, and Data Structures

In order to faithfully reproduce Fuxian counterpoint in a computational setting, it is essential to develop a precise formalization that translates musical concepts into well-defined mathematical structures. This chapter presents the formal framework used to model the rules and stylistic preferences of species counterpoint, serving as the theoretical foundation for the solver's implementation.

The formalization begins with a clear definition of the core musical elements—parts, strata, and voices—which are central to the structure of any polyphonic composition. From these concepts, we introduce the variables, functions, and constraints that govern note pitches, intervals, and motion. These components are then assembled into a constraint satisfaction problem (CSP), where musical rules are enforced through hard constraints, and stylistic guidelines are represented via cost functions.

Throughout this chapter, the formalization is presented in a mathematical language, but always grounded in musical logic. Where applicable, helper arrays and derived functions are introduced to improve the clarity and efficiency of constraint definitions. This chapter lays the groundwork for the solver's algorithmic behavior and ensures a rigorous mapping between musical theory and its computational counterpart.

3.1 Voices, Parts, and Strata

To understand the formal structure, we must first define three foundational concepts: parts, strata, and voices, as initially defined by A. Lamotte[13]. These concepts were developed to manage the increasing complexity of three-part counterpoint compared to earlier formalizations and it remains perfect for counterpoint to any number of parts.

- **Parts**: The most straightforward concept, parts represent the actual musical lines, corresponding to what a person sings or an instrument plays.

Each musical staff in a composition represents a part. In counterpoint compositions, parts include the *cantus firmus* and the counterpoint(s) line(s).

- **Strata**: Unlike parts, strata are an abstract concept primarily useful in the mathematical formalization of Fux's rules. Strata help identify, at any given measure, the relative pitch ranking of voices, determining which voice is the lowest, highest, or any rank in between. The number of strata equals the number of parts. If parts remain within their voice range and do not cross, strata align with parts. However, since parts can cross, the concept of strata becomes particularly useful.

  As explained by A. Lamotte[13], strata enable the application of more nuanced rules, such as defining a relation between the lowest sounding voice and another part, regardless of which part actually plays that note.

  It is important to note that the relative pitch ranking of voices is calculated according to the pitch of the first note in each measure. This means that the rank of strata is calculated per measure.

- **Voices**: This general concept covers both parts and strata. When discussing voices, the reference is collectively to both parts and strata.

Strata Formalization

To ensure a clear mapping between parts and strata, especially when two parts play the same pitch, a bijection is enforced at every measure: each stratum is associated with exactly one part, and vice versa. In case of ties (e.g., two parts playing the same lowest note), precedence is given according to a fixed order: *cantus firmus* first, followed by the counterpoints (cp_1, cp_2, cp_3). For example, if the $cantus firmus$ and cp_1 share the lowest pitch, the lowest stratum is assigned to the $cantus firmus$.

This mapping ensures that strata are well-defined and contain notes from only one part per measure. When sorting notes within a measure, the system orders them from lowest to highest, resolving ties according to the predefined part priority.

In the present work, the implementation of strata has been modified in order to improve the handling of delayed notes, particularly in the fourth and fifth species. In the previous version, strata sometimes failed to reflect the harmonic note actually carrying the weight of the measure (for example, by privileging the suspension rather than its resolution). The new implementation, described in detail in the section 6.1, ensures that each beat is assigned to the musically relevant note, thereby allowing harmonic intervals to be computed correctly in all contexts.

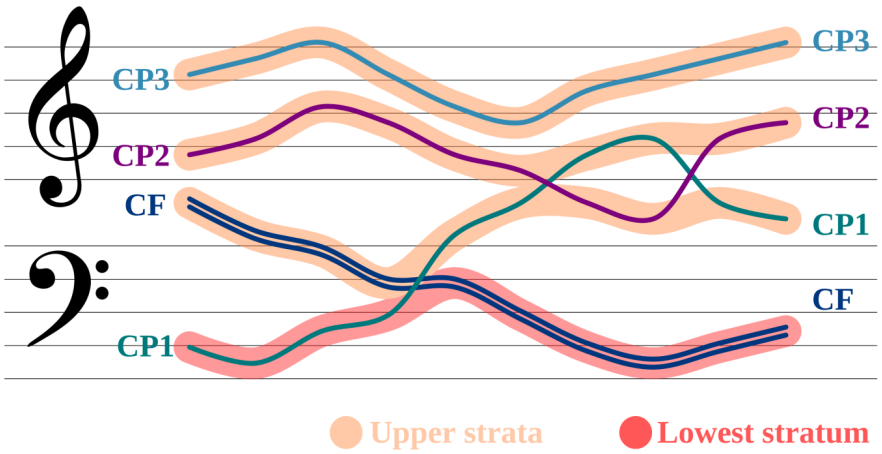

Figure 3.1: Visualisation of parts and strata

Mathematical definition of the notes of the α-th stratum

Given that when $\alpha = 0$, it is the lowest stratum:

$$\begin{aligned} &\forall \alpha \in [0,3] \quad \forall j \in [0, m-1] : N(l[\alpha])[0,j] = X[\alpha] \\ &\text{where } X = sorted([N(cf)[0,j], N(cp_1)[0,j], N(cp_2)[0,j], N(cp_3)[0,j]]) \\ &\text{and } l = [a,b,c,d] \text{ to keep the right stratum notation.} \end{aligned} \tag{3.1}$$

The remaining notes within each measure belong to the same musical part as the first one initially associated with the stratum, ensuring that no single stratum combines notes from multiple distinct parts. The sorted function organizes these notes from the lowest to the highest pitch. In cases where pitches are identical, priority is given first to the *cantus firmus*, followed by the counterpoint lines in their respective order, as previously described.

3.2 Variables and Arrays

As a continuation of the conceptual groundwork on voices, parts, and strata, this section presents the core variables used in the formalization of counterpoint rules.

Although this formalization is mathematical and abstract in nature, it serves as the theoretical basis for the practical implementation, which is discussed later in the thesis. Notably, the computer implementation in C++ introduces helper structures and class hierarchies that are not strictly reflected here. Nevertheless, the main variables and logic remain consistent, and both models yield the same set of solutions, namely, the attribution of MIDI pitches to the counterpoint voices.

Structure of the Constraint Problem

The formalization is defined as a Constraint Satisfaction Problem (CSP), characterized by:

- a set of **variables** (mostly integers),
- their respective **domains** (such as MIDI pitch ranges),
- and a set of **constraints** applied to them.

Most variables are stored in integer arrays, as the pitch of each note is represented by a MIDI number (0 to 127, with 1 semitone per unit). Each note in the generated counterpoints has its own variable, making the model mostly composed of arrays indexed by beat and measure.

Constants and Functions used in the Mathematical Formalization

Before delving into the discussion of the significant arrays to which the constraints will be applied, it is imperative to establish the constants and functions that will facilitate their definition.

Constants

- $\mathcal{B}(v)$ – the set of beats on which a note can be played according to the species of voice v. For the first species, the only beat in a measure is $\{0\}$, as there is only a note on the first beat. For the second species, the set of beats is $\{0, 2\}$. For the third species, it is $\{0, 1, 2, 3\}$. For the fourth species: $\{0, 2\}$. And for the fifth species: $\{0, 1, 2, 3\}$.
- $Cons$ – the set of all consonances, i.e. $\{0, 3, 4, 7, 8, 9\}$, where $Cons_p$ are the perfect consonances, i.e. $\{0, 7\}$, and $Cons_{h\_triad}$ are the consonances of a harmonic triad as defined by Fux, i.e. $\{0, 3, 4, 7\}$.
- Dis – the set of all dissonances, i.e. $\{1, 2, 5, 6, 10, 11\}$.
- $d(v)$ – the duration of a note according to the species of voice v.

Core Variable - Note Pitches: N

The array N is the primary structure in the formalization, storing the MIDI pitch values of each note in the composition. It is addressed as $N[i, j]$, meaning the note at beat i (ranging from 0 to 3) of measure j (ranging from 0 to m, the total number of measures).

To distinguish voices, the notation extends to:

- $N(cf)$: the notes of the *cantus firmus*,

- $N(cp1)$, $N(cp2)$, $N(cp3)$: the notes of counterpoints. Here the first, second, and third counterpoint, respectively
- $N(a)$, $N(b)$, $N(c)$, $N(d)$: notes of strata (from lowest to highest).

By default, when N is mentioned without a voice, it is understood to apply to all parts:

$$N \equiv \forall p \in cf, cp1, cp2, cp3 : N(p) \tag{3.2}$$

This omission can be made for all other arrays.

Although in theory all rules could be defined in terms of N alone, the formalization introduces derived arrays to reflect higher-level musical ideas which make constraints clearer and more efficient: **Harmony**, **Melody**, and **Motion**.

Harmonic Intervals: H_{brut} and H

The array H_{brut} stores the absolute interval, in semitones, between two notes in different voices. It does not account for octave equivalence and can take values from 0 to 127, consistent with the MIDI pitch number system.

$$\begin{gathered}\forall v_1, v_2 \in \{cf, cp_1, cp_2, cp_3, a, b, c, d\}, \forall i \in \mathcal{B}, \forall j \in [0, m-1] \\ H_{brut}(v_1, v_2)[i, j] = |N(v_1)[i, j] - N(v_2)[0, j]|\end{gathered} \tag{3.3}$$

To evaluate intervals independent of octave, the absolute interval H_{brut} is reduced modulo 12. This results in the array H, which contains values from 0 to 11, representing the 12 semitones of the octave.

$$H(v_1, v_2)[i, j]) = H_{brut}(v_1, v_2)[i, j] \mod 12 \tag{3.4}$$

Unless otherwise specified, H is the standard array used for evaluating harmonic intervals or harmonies.

It is important to note that for harmonic constraints, only the first beat of each measure is considered in the compared voice v_2. For convenience, $H(v)$ is the shorthand for $H(v, a)$: the interval between v and the lowest stratum.

Consonance: $IsCons(v)$

A Boolean array $IsCons(v)$ is also defined, indicating whether the interval between voice v and the lowest stratum is consonant (according to predefined sets of allowed intervals):

$$\begin{gathered}\forall i \in \mathcal{B}(v), \forall j \in [0, m-1] \\ IsCons(v)[i, j] = \begin{cases} \top & \text{if } H(v)[i, j] \in Cons \\ \bot & otherwise \end{cases} \\ \text{where } Cons = \{0, 3, 4, 7, 8, 9\}\end{gathered} \tag{3.5}$$

Interval name	Number of semitones	Example	Type of Interval
Perfect prime or perfect octave	0	C – C	Perfect Consonance
Minor second	1	C – D ♭	Dissonance
Major second	2	C – D	Dissonance
Minor third	3	C – E ♭	Imperfect Consonance
Major third	4	C – E	Imperfect Consonance
Perfect fourth	5	C – F	Dissonance
Tritone	6	C – G♭	Dissonance
Perfect fifth	7	C – G	Perfect Consonance
Minor sixth	8	C – A♭	Imperfect Consonance
Major sixth	9	C – A	Imperfect Consonance
Minor seventh	10	C – B♭	Dissonance
Major seventh	11	C – B	Dissonance

Table 3.1: Musical intervals with the number of semitones, examples, and type of interval

Melodic Intervals: M_{brut} and M

The melodic progression of each part is represented through:

- M_{brut}: the signed melodic interval between two successive notes,
- M: the absolute value of that interval.

Formally, the melodic interval when related to a part is given by:

$$\forall p \in \{cf, cp_1, cp_2, cp_3\},\ \forall x \in \{1, 2\},\ \forall i \in \mathcal{B},\ \forall j \in [0, m-1-x]$$
$$M^x_{brut}(p)[i,j] = \begin{cases} N(p)[i+xd, j] - N(p)[i,j] & \text{if } i + xd < 4 \\ N(p)[(i+xd) \bmod 4, j+1] - N(p)[i,j] & \text{if } i + xd \geq 4 \end{cases}$$
$$M^x(p)[i,j] = |M^x_{brut}(p)[i,j]| \tag{3.6}$$

With $d = d(p)[i,j]$. This is done to make the formula easier to read. It is interesting to note that for the first to fourth species, all values contained in the array d(v) are the same because the same type of note is always played (except for in last measure, where it's always a whole note). However, in the fifth species, the notes can be of different types, so in order to generalize the formula to all species, it is important to take the value of d(v) at position [i,j] to calculate $M^x_{brut}(p)[i,j]$.

x, on the other hand, corresponds to the rank of the next note in the sequence. More precisely, it identifies which next note to use when computing the melodic interval from a given note. For example, if $x = 1$, we are interested

in the interval between the current note and the very next note in the part; if $x = 2$, then we compute the interval between the current note and the second note that follows it in the part.

In practice, M^1 is the default, so $M \equiv M^1$. Adding the omission of the parameter p as previously explained in the section 3.2 on the set of variables N, we obtain:

$$M \equiv \forall p \in \{cf, cp_1, cp_2, cp_3\} : M^1(p). \tag{3.7}$$

Motion Between Voices: P

To evaluate how a part moves relative to the lowest stratum, a motion array $P(p)$ is defined which can contain the following value:

- 0 – Contrary motion,
- 1 – Oblique motion,
- 2 – Direct motion,
- -1 – Not applicable (when the part is itself the lowest).

Motion is computed between the current note and the first note of the next measure using an offset $x = b - i$ where b is the number of notes contained in the current measure.

$$\forall p \in \{cf, cp_1, cp_2, cp_3\}, \quad \forall x \in \{1, 2\}, \quad \forall i \in \mathcal{B}, \quad \forall j \in [0, m-1], \quad x := b - i$$

$$motion(p)[i,j] = \begin{cases} 0 & \text{if } (M^x_{brut}(p)[i,j] > 0 > M(a)_{brut}[j]) \\ & \quad \vee (M^x_{brut}(p)[i,j] < 0 < M(a)_{brut}[j]) \\ 1 & \text{if } M^x_{brut}(p)[i,j] = 0 \oplus M(a)_{brut}[j] = 0 \\ 2 & \text{if } (M^x_{brut}(p)[i,j] > 0 \wedge M(a)_{brut}[j] > 0) \\ & \quad \vee (M^x_{brut}(p)[i,j] < 0 \wedge M(a)_{brut}[j] < 0) \\ & \quad \vee (M^x_{brut}(p)[i,j] = 0 = M(a)_{brut}[j]) \end{cases}$$

$$P(p)[i,j] = \begin{cases} -1 & \text{if } A(p)[j] \\ motion(p)[i,j] & \text{if } \neg A(p)[j] \end{cases} \tag{3.8}$$

Bijection Helper: A

To preserve a bijective mapping between parts and strata, even when several notes tie as the lowest, a Boolean array $A(p)$ is used. It specifies whether part p is the lowest stratum at each measure j, using priority order: $cf > cp1 > cp2 > cp3$. Only one part can be assigned as the lowest stratum at any time:

$$\forall j \in [0, m-1]$$

$$A(cf)[j] = \begin{cases} \top & \text{if } N(cf)[0,j] = N(a)[0,j] \\ \bot & \text{else} \end{cases}$$

$$A(cp_1)[j] = \begin{cases} \top & \text{if } (N(cp_1)[0,j] = N(a)[0,j]) \wedge \neg A(cf)[j] \\ \bot & \text{else} \end{cases}$$

$$A(cp_2)[j] = \begin{cases} \top & \text{if } (N(cp_2)[0,j] = N(a)[0,j]) \wedge \neg A(cf)[j] \wedge \neg A(cp_1)[j] \\ \bot & \text{else} \end{cases}$$

$$A(cp_3)[j] = \begin{cases} \top & \text{if } \neg A(cf)[j] \wedge \neg A(cp_1)[j] \wedge \neg A(cp_2)[j] \\ \bot & \text{else} \end{cases} \tag{3.9}$$

Fifth Species and the S Array

While the first to four species maintain a consistent rhythmic nature, the fifth species introduces variable rhythms (e.g., suspensions, syncopations). Therefore, an additional array S is defined to specify the species constraint of each note:

$$\forall \rho \in \text{positions}(m) :$$

$$S[\rho] = \begin{cases} 0 & \text{if } N[\rho] \text{ is not constrained by any species} \\ 1 & \text{if } N[\rho] \text{ is constrained by the first species} \\ 2 & \text{if } N[\rho] \text{ is constrained by the second species} \\ 3 & \text{if } N[\rho] \text{ is constrained by the third species} \\ 4 & \text{if } N[\rho] \text{ is constrained by the fourth species} \end{cases} \tag{3.10}$$

This allows the model to enforce the correct rules for each type of note behavior within the same part.

Modeling Preferences: Costs C

Fux's treatise includes both hard rules (strictly enforced) and soft preferences (stylistic guidelines). To formalize preferences, the model introduces cost variables. These cost arrays quantify violations of preferences. When searching for solutions, the solver minimizes the sum of costs, turning the problem into an optimization task. In the mathematical framework used to formalize constraints throughout this thesis, cost functions are denoted by the symbol C. It is worth noting that most of these costs are represented as arrays of variables, with each element corresponding to a separate cost assigned per measure:

$$\forall j \in [0, m-1]$$

$$C[j] = \begin{cases} 0 & \text{if the preference is respected at measure j} \\ \mathbb{N}^+ & \text{otherwise} \end{cases} \tag{3.11}$$

Examples include: $C_{prefer\_harmonic\_triad}, C_{prefer\_harmonic\_triad}$, among others. All cost variables form the set C, which is crucial for guiding the solver toward musically satisfying results.

This comprehensive structure of variables ensures that the formalization accurately captures both the rigid rules and stylistic nuances of Fux's counterpoint, and provides a solid mathematical foundation for the subsequent computer implementation.

3.3 Notational Clarifications and Corrections

In the process of refining the formalization presented in this thesis, I made several adjustments to the mathematical notation used in previous work to improve clarity, consistency, and accuracy. These changes focus particularly on indexing conventions and the way ranges are expressed when referring to sequences of notes, measures, or harmonic intervals.

In earlier versions of the formalization, there was an inconsistent use of notation when referencing the boundaries of an array or range. For example, both $N[0, m)$ and $N[0, m-1]$ were used, despite representing the same note. To resolve this, I adopted a consistent approach aligned with standard mathematical and programming conventions:

- Indexing starts at 0, meaning the first element is N[0].
- When referring to a range, I now consistently use $N[0, m-1]$, explicitly including both the start and end indices, rather than the half-open interval $[0, m)$.

This change not only improves readability but also aligns the formalization with the indexing used in the C++ implementation, thereby reducing the risk of off-by-one errors or misinterpretations.

In fact, I believe that some errors in the previous version of the formalization may have been caused by such inconsistencies. For instance, in the definition of rule 1.H7 from the thesis of L. Cleenewerk and D. de Patoul[5], for three voices, the penultimate harmonic interval is incorrectly referred to as $H[0, m-1]$, which actually denotes the last harmonic interval. To correctly refer to the penultimate harmonic, the proper indexing should be $H[max(\mathcal{B}), m-2]$, where $max(\mathcal{B})$ selects the last beat of the measure, and $m-2$ correctly references the second-to-last measure. I have corrected this and similar errors throughout the formalization.

These notational clarifications and corrections are essential for ensuring that the mathematical model matches the intended musical behavior, and they help prevent errors both in theoretical reasoning and in practical implementation.

Chapter 4

Program architecture

This chapter provides an overview of the program architecture, as established in previous work. The architecture, originally introduced by L. Cleenewerk and D. de Patoul in their master thesis [5], focuses on the C++ implementation designed for counterpoint composition. It takes advantage of object-oriented programming principles to create a structured and maintainable system capable of handling the complexities of counterpoint theory.

4.1 Inheritance and Class Structure

The program utilizes an inheritance-based structure to manage different elements of counterpoint theory. Central to this structure is the Voice class, which serves as a base class for various types of voice, such as the *cantus firmus* and different species of counterpoints. This approach centralizes common structural elements and behaviors, reducing redundancy and enhancing code maintainability.

- **Voice Class**: The foundational class that encapsulates common properties and methods shared by all types of voices.
- **Part Class**: Inherits from Voice and serves as a base for different species of counterpoints, providing a consistent interface and shared functionality.
- **Species-Specific Classes**: Classes such as `FirstSpeciesCounterpoint` and `SecondSpeciesCounterpoint` inherit from `Part` and implement species-specific constraints and behaviors.

This hierarchical structure allows for the efficient application of constraints while maintaining a clear and consistent interface.

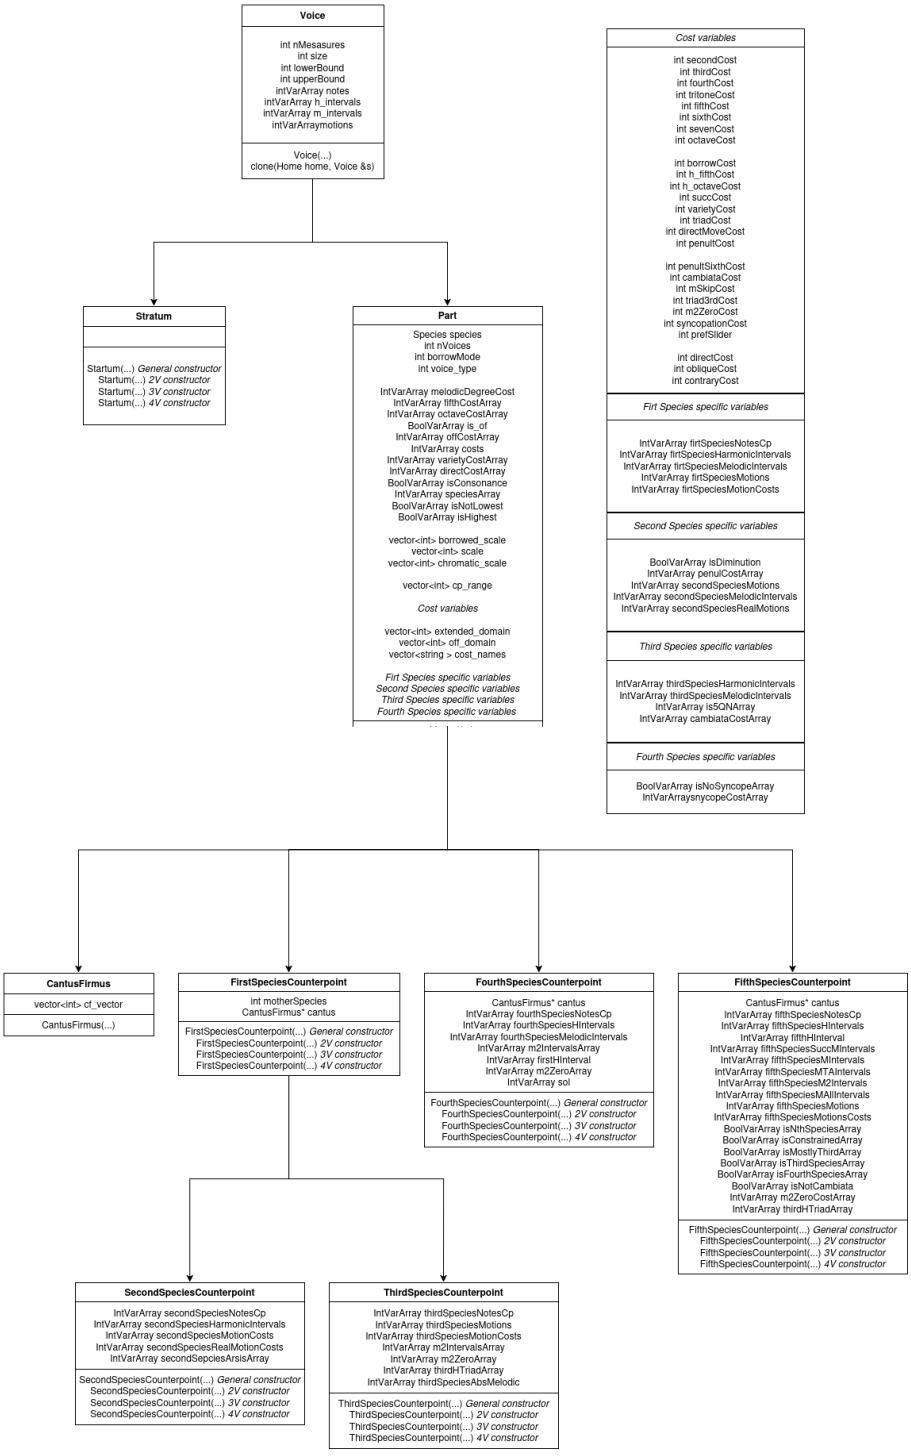

Figure 4.1: UML-style diagram of the Voice class hierarchy

Note on the `Part` class: Beyond inheriting from `Voice`, `Part` functions as a shared interface: it concentrates the common state, helper predicates/arrays, and cost structures that all species rely on, so subclasses don't have to re-implement the plumbing. To keep the diagram legible, these members are grouped together in the large rectangle adjacent to `Part` rather than crowded into the class box itself.

4.2 Managing Context and Constraints

One of the key challenges in implementing counterpoint theory is managing the context in which constraints are applied. The set of rules depends on parameters such as species and the number of voices. The program addresses this challenge through a combination of inheritance and multiple constructors.

Each species class has constructors tailored to different numbers of voices, such as two, three, and four voices. These constructors call a shared, internal constructor that applies constraints common to all instances of that species, regardless of the number of voices. This approach isolates different contexts and ensures that the appropriate set of constraints is applied automatically when a new counterpoint object is instantiated.

4.3 Hierarchy of Problem Classes

The program defines an abstract base class, `CounterpointProblem`, which is a child of the Gecode class `Space`. This class is implemented by three concrete classes: `TwoVoiceCounterpoint`, `ThreeVoiceCounterpoint`, and `FourVoiceCounterpoint`. Each of these classes handles the constraints that apply to the composition as a whole, depending on the number of voices.

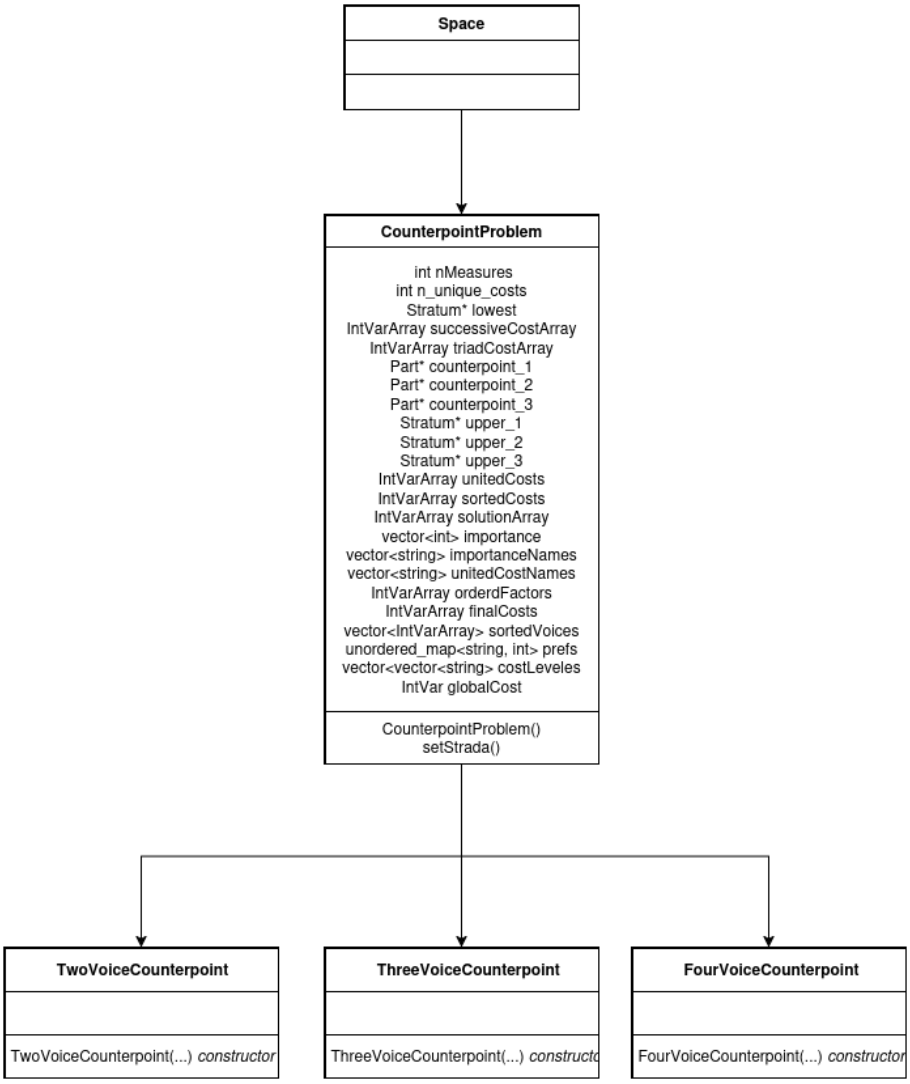

Figure 4.2: UML-style diagram of the CounterpointProblem class hierarchy

4.4 Flow of the Program

To illustrate the flow of the program, consider the example of creating a three-voice counterpoint problem with a counterpoint of the third species and another of the first species:

1. **Problem Parameters**: The user defines the problem parameters as the *cantus firmus*, the number of voices, their species, etc.

2. **Problem Creation**: The `create_problem` function dispatches the creation of the appropriate `CounterpointProblem` object according to the parameters given. In this example, a `ThreeVoiceCounterpoint` object is created.

3. **Constructor Invocation**: The `ThreeVoiceCounterpoint` constructor is invoked, which calls the necessary functions to construct the Constraint Satisfaction Problem (CSP):

   - The `CounterpointProblem` constructor. As a child of `CounterpointProblem` class, `ThreeVoiceCounterpoint` constructor call the constructor of its parent, which creates general variables, arrays and call the `CantusFirmus` constructor.
   - The `counterpoint` objects are created using the `create_counterpoint` function with the appropriate arguments which call the right constructor given the context similarly to the `create_problem` function. In this scenario, the function is called twice:
     a) For the creation of the first species counterpoint object, it invokes the relevant counterpoint constructor, specifically the three-voice constructor of the `FirstSpeciesCounterpoint` class. This constructor starts by calling the general constructor of the `FirstSpeciesCounterpoint` class, which inherits from the `Part` class. The `Part` class, in turn, inherits from the `Voice` class. This ensures that all common variables and constraints from the `Voice` and `Part` classes are applied and then those of the `FirstSpeciesCounterpoint` class. After this, the three-voice specific constructor proceeds to post the constraints specific to first species counterpoints in three-voice compositions.
     b) For the creation of the third species counterpoint object, it follows a similar process. Since the `ThirdSpeciesCounterpoint` class inherits from the `FirstSpeciesCounterpoint` class, it first calls the general constructor of the `FirstSpeciesCounterpoint` class before proceeding to its constructor. The call cascade is then the same as explained above from the general constructor of `FirstSpeciesCounterpoint`.

4. **CSP Construction**: The CSP is now constructed, and the CounterpointProblem pointer is returned by the `create_problem` function. This pointer will later be used to start the search for solutions.

Chapter 5

Model Validation

After reviewing all the essential concepts of counterpoint and how the program works, it is now time to present my contribution to the project: the systematic testing of the program and the correction of implementation errors. While the theoretical framework and formal constraints were already defined, the proper functioning of the system required careful validation through practical execution. My role consisted in thoroughly testing the program across a variety of counterpoint configurations, identifying inconsistencies between expected and actual behavior, and resolving logical or computational errors in the code. This work was essential to ensure that the system reliably applies the rules of counterpoint across different species and voice combinations, in line with both the theoretical model and musical expectations.

We have validated and corrected the formal model of Fux counterpoint that was developed in three previous master theses. Validations were done in four directions:

1. Validation with respect to implicit knowledge. Fux does not make all rules explicit in his treatise. He assumes much implicit knowledge of music theory and counterpoint. We have corrected and extended the rules with respect to this implicit knowledge.

2. Validation of the Fux rules with respect to the musical examples in the Fux treatise. The Fux treatise has many musical examples. The examples do not always respect the rules that Fux gives in the text of the treatise. We consider that Fux, being a musician, gives correct examples. But since Fux is not a mathematician, the textual explanation of the rules is not always precise or complete. We have made a technical analysis of all the examples with respect to the formal model. We use the concept of MUS (Minimal Unsatisfiable Subset) from the theory of constraint programming. This lets us determine which rules must be changed when we find an example that does not satisfy the formal model. The results of the MUS analysis are summarized in section 5.2.

3. Validation of the Fux rules with respect to the treatise of Noël Gallon and Marcel Bitsch [9]. This treatise presents Fux counterpoint in a more explicit way than the Fux treatise. In the Bitsch treatise, all rules are given explicitly

and numbered, and given a much more precise definition than what Fux has given.

4. Correction of errors in the previous formalization. In the previous formal model, we have discovered occasional errors in the constraint code that implements the rules. For example, incorrect or incomplete translation of the mathematical definitions into constraint code, or incorrect mathematical definition of textual rules. We have corrected all these errors.

The first three validations were done in close collaboration with Karim Haddad. Every single Fux rule was discussed in detail with Dr. Haddad and studied in terms of its musicality (does it give correct musical results) and in terms of the corresponding rules in the treatise of Gallon and Bitsch. Any ambiguity and error was removed to the best of our ability. Occasionally this required a musical judgement, which was decided upon after discussion with Dr. Haddad. The result of these discussions for all the rules are given in chapter 6. The full, corrected model is given in chapter 7.

5.1 Unit Tests

I started by implementing a set of unit tests to verify the correct behavior of individual constraints in the counterpoint solver. The aim was to ensure that each rule functioned as expected when applied across various counterpoint configurations, including different numbers of voices (two, three, or four) and species (first, second, etc.). For each tested rule, I created example figures that intentionally violated the constraint and checked whether the solver correctly failed to find a valid solution.

I implemented that in the FuxTest.cpp file which had already been created by L. Cleenewerk and D. de Patoul for their own test. To build these test cases, I defined a new problem instance with a *cantus firmus* and explicitly fixed the solution notes in the counterpoint voices so that the targeted constraint was broken. The rationale was that, if the constraint was correctly implemented, the solver should reject the solution.

For example, let's take rule **1.H1** which says: *"All notes on the downbeat are consonant with the notes (on the downbeat) of the lowest stratum."* Which is formalized mathematically as:

$$\forall j \in [0, m-1] \quad H[0, j] \in Cons \tag{5.1}$$

The test of this rule on the two voice counterpoint with the first species is:

```
1   void FuxTest::test_1H1_2v_1sp() {
2       cout << "Start test 1H1 2v 1sp..." << endl;
3       // define dissonant intervals
4       int dis[] = {1, 2, 5, 6, 10, 11};
5       // define the species
6       spList = {FIRST_SPECIES};
7       // define the voice types (=pitch range):
8       // {(6 * v_type - 6) + cf[0], (6 * v_type + 12) + cf[0]}
9       v_type = {3};
10      // Test that dissonant notes are forbidden
11      for (int interval : dis) {
12          for (size_t i = 0; i < cfSize; i++) {
13              CounterpointProblem* problem = create_problem(cantusFirmus,
                    ↪ spList, v_type, melodic_params, general_params,
                    ↪ specific_params, importance, borrowMode);
14              int note = cantusFirmus[i] + 12 + interval; // note is dissonant
15              rel(problem->getHome(), problem->getSolutionArray()[i], IRT_EQ,
                    ↪ note); // fix the note i
16              if (has_solution(problem)) {
17                  std::cerr   << "/!\\ ERROR test 1H1 2v 1sp: It exists a
                        ↪ solution but it shouldn't with the following
                        ↪ configuration:\n"
18                              << "Cantus firmus: ";
19                  printVector(cantusFirmus);
20                  std::cerr   << "Solution array: ";
21                  printIntVarArray(problem->getSolutionArray());
22                  std::cerr   << "> Dissonant harmonic at the mesure " << i <<
                        ↪ std::endl;
23              }
24              delete problem;
25          }
26      }
27      cout << "End test 1H1 2v 1sp..." << endl;
28  }
```

Listing 5.1: 1.H1 Test on two voice counterpoint with first species

The same tests obviously exist for all other counterpoint configurations involving this rule.

Unfortunately, this approach quickly showed its limitations. It was both time-consuming and difficult to isolate constraints, as solver failure could result from the interaction with other rules, not necessarily the one being tested.

As a result, I implemented unit tests for only about ten constraints before deciding to adopt a different, more effective method for analyzing and correcting errors in the system. After this initial testing phase, I explored more effective strategies for debugging and verifying constraint behavior, which will be presented in the subsequent chapters.

Managing Subclass Conflicts When Switching Voice Configurations

One of the technical challenges encountered during the implementation of unit tests was the inability to run multiple tests sequentially in a single execution, particularly when these tests involved different numbers of voices. As previously explained, each configuration (two, three, or four voices) corresponds to a different subclass of the `CounterpointProblem` class: `TwoVoiceCounterpoint`,

ThreeVoiceCounterpoint, and FourVoiceCounterpoint. These subclasses each initialize only the attributes required for their specific configuration. For instance:

- TwoVoiceCounterpoint initializes only Part* counterpoint_1 and Stratum* stratum_1;
- ThreeVoiceCounterpoint initializes Part* counterpoint_1, Part* counterpoint_2, Stratum* stratum_1 and Stratum* stratum_2;
- FourVoiceCounterpoint adds Part* counterpoint_3 and Stratum* stratum_3.

Because these attributes are not shared across subclasses and are initialized only when explicitly declared in the relevant class, running multiple tests in sequence, each requiring a different subclass, led to undefined behavior or segmentation faults when accessing uninitialized attributes. The root of the problem lies in the fact that the solver expects all Part* pointers to be valid, regardless of whether they are used in a specific test.

To resolve this, I chose to explicitly initialize all unused Part* and Stratum* pointers to nullptr. This ensured that the solver could safely detect and skip over unused voices, avoiding memory access issues and allowing different CounterpointProblem subclasses to be instantiated in a single execution without error.

```
1   ThreeVoiceCounterpoint::ThreeVoiceCounterpoint(vector<int> cf, vector<Species
      ↪ > sp, vector<int> v_type, vector<int> m_costs, vector<int> g_costs,
2   vector<int> s_costs, vector<int> imp, int bm) :
3       CounterpointProblem(cf, -1, m_costs, g_costs, s_costs, imp, THREE_VOICES)
          ↪ {
4       species = sp;
5
6       //initialize upper strata
7       upper_1 = new Stratum(*this, nMeasures, 0, 127, lowest->getNotes(),
          ↪ THREE_VOICES);
8       upper_2 = new Stratum(*this, nMeasures, 0, 127, lowest->getNotes(),
          ↪ THREE_VOICES);
9       upper_3 = nullptr;
10
11      //create counterpoints
12
13      counterpoint_1 = create_counterpoint(*this, species[0], nMeasures, cf, (6
          ↪  * v_type[0] - 12) + cf[0], (6 * v_type[0] + 12) + cf[0], lowest,
14          cantusFirmus, v_type[0], m_costs, g_costs, s_costs, bm, THREE_VOICES)
              ↪ ;
15      counterpoint_2 = create_counterpoint(*this, species[1], nMeasures, cf, (6
          ↪  * v_type[1] - 12) + cf[0], (6 * v_type[1] + 12) + cf[0], lowest,
16          cantusFirmus, v_type[1], m_costs, g_costs, s_costs, bm, THREE_VOICES)
              ↪ ;
17      counterpoint_3 = nullptr;
18      ...
19  }
```

Listing 5.2: ThreeVoiceCounterpoint constructor with unused part and stratum initialized to nullptr

5.2 Testing Fux Examples using MUS

Motivation

After the limitations of the unit testing approach became apparent, I shifted to a new strategy based on Minimal Unsatisfiable Subsets (MUS). This pivot was motivated by a surprising and problematic observation: although the solver was designed to model Fuxian counterpoint, it frequently failed to validate examples taken directly from Fux's treatise *Gradus ad Parnassum*.

One of the most frustrating aspects of the previous work on the project was that the solver almost never returned the solution actually given by Fux, even when provided with the exact same *cantus firmus*. In principle, if the constraints implemented in the solver are truly based on Fux's theory, then the examples from his treatise should at the very least be accepted as valid. The fact that this was not the case indicated a serious gap between the theoretical model and its computational implementation.

Using Fux's examples as test material has a major advantage: these figures are guaranteed to be correct. As the system is explicitly built on Fux's rules, his published exercises constitute a reliable reference. Therefore, if the solver fails to validate one of these examples, the problem necessarily lies in the formalization—whether due to an error in logic, a misinterpretation, or an overly rigid encoding of the rule set.

Naïve Approach: Activating Constraints One by One

To identify which constraints were responsible for the failure of each figure, I first attempted a naïve diagnostic method: enabling one constraint at a time. I modified the system to allow individual activation and deactivation of each rule, and ran the solver repeatedly for each figure, checking whether a solution could be found when only a single constraint was active.

During this process, I discovered that some constraints were not documented or explained in the previous master thesis. These rules appeared in the code but were not referenced in the theoretical material available. To keep track of these, I labeled them as UX, where "U" stands for "unknown" and "X" is a unique identifier for each undocumented constraint. These UX rules are marked accordingly in the results table presented later in this chapter. A more detailed discussion of these unknown constraints and their possible roles will be provided in the next chapter.

Despite offering some preliminary insights, this one-constraint-at-a-time method has limits. Constraints in a system often interact in subtle ways. For instance, a solution might be possible when only constraint C_1 is active, or when only C_2 is active, but still fail when both are active together. This means that testing each rule in isolation is insufficient: it fails to detect combinatorial conflicts between constraints, which are often the true source of the problem.

MUS: A Systematic and Reliable Strategy

To address these limitations, I implemented a method based on Minimal Unsatisfiable Subsets (MUS). A MUS is defined as the smallest set of active constraints that, when combined, render a problem unsolvable, i.e., no valid solution can be found. Importantly, all constraints in the MUS are necessary for the failure: removing any one of them makes the figure solvable again.

This approach allows us to identify not just individual faulty rules, but also specific interactions between rules that cause a breakdown in the system. It provides a far more precise diagnostic tool than the earlier method and helps isolate the exact causes of unsatisfiability.

Implementation Details

The implementation of this MUS-based approach follows a structure very similar to the one used during the unit testing phase. However, to keep this new strategy independent and more focused on testing real musical examples, I decided to re-implement it in a dedicated file, named `figureTests.cpp`. This file contains a separate function for each Fuxian figure that could be encoded in our system. Each function defines the *cantus firmus*, fixes the counterpoint voices according to the notes provided by Fux, and runs the solver under the full set of constraints.

```
1    void FigureTests::test_2v_1sp_fig22() {
2        cout << "Start test_2v_1sp_fig22" << endl;
3        spList = {FIRST_SPECIES};
4        cantusFirmus = {57,60,59,62,60,64,65,64,62,60,59,57};
5        cp =           {69,64,67,65,64,72,69,71,71,69,68,69};
6        v_type = {1};
7        findAllMUSes();
8    }
```

Listing 5.3: Figure Test of the figure 22 given by Fux [8]

As before, some examples from Fux's treatise had to be excluded due to stylistic or rhythmic complexities that exceeded the capabilities of the solver. In addition, all fifth species examples had to be modified, since the current program does not yet handle certain rhythmic patterns and ornaments. In this version of the solver, the fifth species can only be composed using elements from the third species (quarter notes) and the fourth species (half notes tied to create syncopation). Consequently, every tested fifth species exercise was adapted to fit this restricted rhythmic vocabulary.

Figure 5.1: Original version of the fifth species voice from the figure 82 [8, p.64]

Figure 5.2: Modified version of the fifth species voice from the figure 82 to be well handled by FuxCP [8, fig.82]

In order to enable MUS extraction, I first modified the program so that each constraint could be individually switched on or off. Every call to a constraint function has been wrapped inside an `if` block, controlled by a Boolean entry in the global array `activeConstraints`.

```
1     // G4 :
2     if (activeConstraints[SP1_G4]) {
3         G4_counterpointMustBeInTheSameKey(home, this);
4     }
```

Listing 5.4: Activation control of the G4 constraints in the FirstSpeciesCounterpoint.cpp file

Each constraint is assigned a unique identifier in the constraints enumeration defined in `utilities.hpp`. This enumeration ensures a one-to-one mapping between constraints, their activation state in `activeConstraints`, and their textual label in the constraintNames vector used for debugging and MUS reporting. The solver can therefore dynamically activate or deactivate any subset of rules by simply adjusting the entries of the `activeConstraints` vector before posting the constraints.

The MUS extraction algorithm that I implemented is based on the first method described in the article *Towards Efficient MUS Extraction* [2]. In my implementation, this corresponds to the function `minimize()`, which is directly inspired by the original algorithm presented in the paper. The original version was designed to return only one Minimal Unsatisfiable Subset per call, whereas I adapted and extended it to compute all MUS associated with a given figure. This modification was essential to obtain a comprehensive view of the possible minimal subsets of constraints that lead to failure.

The MUS search itself is implemented in the function `findAllMUSes()`. The algorithm begins by enabling the full set of constraints and then explores subsets using a breadth-first strategy. For each candidate set:

1. The solver checks satisfiability with `is_unsat(current)`.
2. If the set is unsatisfiable, the function `minimize(current)` extracts a minimal unsatisfiable subset (MUS).

3. This MUS is stored, and new candidate sets are generated by removing one constraint at a time from it.

4. Each new set is added to the queue if it has not been visited already.

This iterative process guarantees that all MUSes are discovered. Finally, the indices of each MUS are mapped back to their human-readable names using `get_constraint_name(cons)` and printed to the console.

Listing 5.5: Pseudo-code of the all MUS finder algorithm used

```
//Main Function
Function findAllMUSes():
    //Initialize:
    cons_set ← {0, 1, 2, ..., N-1}  //all constraint
        indices
    mus_found ← empty set of sets
    visited ← empty set of sets
    queue ← empty queue
    Enqueue cons_set into queue
    Add cons_set to visited
    While queue is not empty:
        current_set ← dequeue from queue
        If is_unsat(current_set) == FALSE:
            //Current set is satisfiable, skip it and go to
                while loop
            Continue
        mus ← minimize(current_set)
        If mus not in mus_found:
            Add mus to mus_found
            #Generate new candidate sets by removing one
                constraint at a time
            For each constraint c in mus:
                next_set ← current_set without c
                If next_set not in visited:
                    Add next_set to visited
                    Enqueue next_set into queue
    //Output all MUSes found
    For each mus in mus_found:
        Print "MUS found:"
        For each constraint c in mus:
            Print get_constraint_name(c)

//Helper Functions
Function minimize(constraint_set):
    mus ← copy of constraint_set
    For each constraint c in mus:
        trial ← mus without constraint c
        If is_unsat(trial):
            mus ← trial
```

```
        Return mus

    Function is_unsat(constraint_set):
        Deactivate all constraints
        For each constraint c in constraint_set:
            Activate constraint c
        problem ← create new constraint satisfaction problem
        If problem has no solution:
            Return TRUE  //the set is unsatisfiable
        Else:
            Return FALSE //the set is satisfiable
```

Thanks to this algorithm, it was possible to identify exactly which constraints—or combinations thereof—block the validation of a figure.

5.3 Results and Interpretation

The first interesting result is that the MUS extraction algorithm never identified any subset containing more than one constraint. This suggests that, despite our apprehensions, the constraints in the system are largely independent, at least with respect to the Fuxian figures tested. In other words, solver failures can generally be attributed to a single rule, rather than a problematic interaction between multiple constraints. This independence both simplifies debugging and supports the modular structure of the current formalization.

To synthesize the results of the MUS-based testing approach, I compiled a table that presents, for each Fuxian figure tested, the specific constraint that prevented the solver from validating the example. This table was constructed directly from the output of the MUS extraction algorithm, which, for every figure, printed the corresponding Minimal Unsatisfiable Subset—in this case, always reduced to a single constraint, as previously discussed. By aggregating this output, I was able to mark, with an "X", each instance where a constraint was solely responsible for the solver's failure on a given figure. The resulting table provides a clear and systematic overview of which rules are too restrictive, incorrectly implemented, or potentially misaligned with Fux's treatise, and offers a basis for further revision and refinement of the constraint system.

Figure 5.5: Derogated rules for four voice counterpoint

The tables above summarize the results of the MUS-based analysis performed on a selection of Fuxian figures. The first row of the tables list the figure numbers as they appear in the English edition of *Gradus ad Parnassum* by Alfred Mann [8]. The second row indicates the voice configuration and species of each example, following the format: number of voices (e.g., 2v, 3v, 4v) and species type (e.g., 1sp, 2sp, 3sp, ...).

Each row from the third line onward corresponds to a specific constraint. The constraint naming convention follows the pattern:
<File name>_<Constraint name>_<Voice number> with <Voice number> specified only if the rule is called in the specific number of voice constructor of the class related to the filename, otherwise, it means that the rule is called in the general constructor. This structure makes it easy to identify where each rule is implemented in the codebase and to which configuration it applies. For instance, a row labeled SP3_3H1_2V refers to the constraint 3.H1 implemented in the file ThirdSpeciesCounterpoint.cpp, specifically for the two-voice configuration.

The cells within the table are marked with an "X" when the corresponding figure violates the associated constraint. In other words, an "X" indicates that the MUS analysis identified this rule as a reason why the solver failed to accept the given Fuxian example. Cells left blank imply that the constraint was not part of any MUS for that figure. If a column is green, it means that this figure satisfiable all the rule applied to it.

This table provides a clear diagnostic overview of the mismatch between the implemented rule set and the original examples from Fux's treatise, and serves as a guide for identifying which constraints may require revision, relaxation, or refinement. The next chapter presents this diagnostic table and provides detailed commentary on selected examples.

Chapter 6

Rule-by-Rule Review of Validation Results

This chapter focuses on a detailed review of the constraints implemented in the solver, with particular attention to two categories of rules identified during the MUS-based analysis. First, I address the undocumented rules—constraints present in the codebase but not included or explained in the previous master thesis. These were labeled UX during testing (for "Undocumented") and require clarification regarding their purpose, validity, and relevance to Fuxian counterpoint. Second, I examine the derogated rules—that is, the constraints that were violated by one or more Fuxian figures during testing. For each of these, I analyze whether the failure was due to a flaw in implementation, an overly strict formalization, or a deeper misalignment with Fux's treatise.

The goal of this chapter is twofold: to bring transparency to the full set of constraints governing the solver's behavior, and to propose corrective actions for rules that either lack justification or have been shown to block valid Fuxian examples. This review is a key step toward improving the solver's accuracy and consistency with historical counterpoint practice.

Each rule will be presented using a two-part format. First, a brief sentence in English will describe the intended function or effect of the rule in musical terms, as far as it can be inferred from the code or behavior of the solver. This will be followed by the mathematical formalization of the constraint as implemented, to precisely capture how it operates within the system. This structure ensures both conceptual clarity and technical accuracy, allowing for a critical assessment of each rule's relevance and correctness.

6.1 Delayed Notes and Stratum

Many inconsistencies identified by MUS trace back to when a note is considered to "count" for rule checking. In Fuxian practice—especially in fourth species and parts of fifth—notes are often delayed across strong beats by ties; this is the classic syncopation (also called a ligature in English translations of Gradus ad

Parnassum). If the model evaluates intervals and motions strictly at onsets, a sustained (delayed) note can be misread as "absent," producing false violations; if it evaluates everywhere, rules can fire multiple times per beat and inflate conflicts.

To resolve this, we introduce the notion of stratum: a time grid aligned with arsis/thesis (weak/strong) positions on which harmonic and motion rules are evaluated. Delayed notes contribute their pitch at the appropriate stratum boundary (typically the strong beat they tie into), while purely rhythmic detail between strata is ignored by rules that are not meant to see it. This separation between raw events and stratum-aligned evaluation restores the intended reading of suspensions and syncopations, makes parallel/melodic checks well-defined across voices, and eliminates spurious MUS caused by timing ambiguities. The remainder of this section formalizes the stratum mapping and updates the affected rules accordingly.

Delayed Notes Definition

A note is delayed when its attack on the thesis is not a fresh onset but the continuation (tie) of the previous arsis from the preceding bar. This creates the classical preparation $\rightarrow$ suspension $\rightarrow$ resolution pattern: the tied note sounds on the thesis (often forming a dissonance against the other voice[s]) and resolves by step (joint) on the next arsis.

If the resolution is not achieved by a joint degree (i.e., no stepwise motion into the arsis), then the note is not considered a true delayed note. In such cases, the continuation (tie) of the previous arsis is instead treated as part of the harmony of the measure. This distinction was not correctly handled in the previous implementation, which is why the stratum assignment had to be revised. The updated approach, described in the next subsection, ensures that only proper suspensions with joint resolution are recognised as delayed notes, while non-joint continuations are incorporated directly into the harmony.

Stratum Implementation

In the previous implementation of the solver, strata were defined only at the level of measures. Concretely, only the first beat of each measure contained a note for each stratum, and all other beats in that measure were left undefined. Furthermore, the harmonic interval at each beat was systematically computed with respect to the lowest voice in the texture.

This design led to important limitations. For example, consider a two-voice counterpoint where the cantus firmus is placed in the upper voice and the counterpoint is written in the third species in the lower voice. If one wishes to evaluate the harmonic interval formed by the final note of the penultimate measure, the previous implementation incorrectly computed it between the cantus firmus and the *first* note of the penultimate measure of the third-species line. The actual last note of that measure, which should bear the harmonic weight at

that position, was ignored. As a result, several rules involving penultimate-beat checks could not be evaluated correctly.

To overcome this limitation, I redesigned the stratum assignment so that each beat is explicitly associated with the note actually sounding at that moment. For example, in the first species, where a whole note spans the full measure, every beat of the measure is assigned to the same note. In species with shorter rhythmic values (e.g., second, third, or fifth species), each beat is linked to the corresponding played note. In the case of delayed notes (suspensions), the assignment has also been corrected: the thesis is replaced, where appropriate, by the resolution or jointly treated with the arsis, according to the true harmonic function described in the previous subsection.

This new approach ensures that the strata reflect the actual musical reality at every beat. Harmonic intervals can now be computed consistently for all positions, including cases such as the penultimate note of a measure, which were previously mishandled. At the same time, the treatment of delayed notes has been aligned with their functional role, thereby integrating rhythmic and harmonic accuracy into a single coherent implementation.

6.2 Undocumented Rules

During the MUS-based analysis, I identified several constraints that were not documented or explained in the previous master thesis while present and active in the code. For clarity, I labeled them as UX (for "Undocumented") followed by a unique number. This section aims to review these undocumented rules, explore their possible purpose or origin, and assess whether they should be retained, modified, or removed to improve the solver's fidelity to Fuxian counterpoint.

STRATUM_1H12_UPPER (1.H12)

In three- and four-voice counterpoint, the final chord must not contain a minor third.
This rule applies to any species in three and four voice counterpoints.

$$H[0, m-1] \neq 3$$

This rule was first introduced into the formalisation by A. Lamotte[13] as **1.H12**, but was later omitted in the thesis of L. Cleenewerk and D. De Patoul[5]. Let's examine it again.

Fux consistently prefers the major third for the final chord, regardless of the mode of the counterpoint:

"If you mean the minor third don't you realize that is not capable of giving a sense of conclusion" [8, p. 80].

"Take a major third instead; for the minor third, being a more perfect consonance, is still less suitable for the end" [8, p.82].

In contrast, other composers such as Bitsch use the minor third freely when it better fits the mode.

In the present work, it has been explicitly reintroduced, as the aim is to remain as close as possible to Fux's style.

V4_U2 (1.H13)

For every pair of upper voices, the thesis note of each measure must never form a minor second interval.

$$\begin{gathered} \forall j \in [0, m-1], \quad s_1, s_2 \in \{b, c, d\} \\ H(s_1, s_2)[0, j] \neq 1 \end{gathered} \tag{6.1}$$

In traditional counterpoint, the minor second interval is considered a dissonance and is therefore prohibited in this position. Since this principle also applies to three-voice counterpoint, the rule has been extended accordingly and incorporated into its constraint set. Following the established rule nomenclature, it has been designated as rule **1.H13**.

From an implementation perspective, the rule was originally enforced only in `FourVoiceCounterpoint.cpp`. To ensure its scope covers three-voice counterpoint as well, it is now also explicitly called in `ThreeVoiceCounterpoint.cpp`.

SP3_U1 (3.M2)

No melodic interval between 9 and 11 semitones.
This rule applies to all third-species counterpoints.

$$\begin{gathered} j \in [0, m-2] \\ M[3, j] \notin \{9, 10, 11\} \end{gathered} \tag{6.2}$$

This rule is the same as **1.M2**, but applied to the third species. It is supported by Bitsch:

"27 - Melodic intervals. Rules concerning two successive notes.
A. The following are permitted:
- [...]
B. The following are prohibited:
- [...]
- intervals exceeding the minor sixth (except for the perfect octave)" [1] [9, p.18-19].

[1] Translated from French

In the previous implementation, this rule was applied only to the interval between the last note of a measure and the first note of the following measure. However, as Bitsch states, this restriction applies to *every* melodic interval. I therefore extend the rule as follows:

$$\begin{gathered} \forall i \in \mathcal{B}, \quad \forall j \in [0, m-2], \\ M[i,j] \notin \{9, 10, 11\} \end{gathered} \tag{6.3}$$

The implementation has been updated to follow this new formalisation, ensuring that all melodic intervals are checked rather than only those across barlines.

Despite its resemblance to rule **1.M2**, this rule has been added to the complete set of rules under the designation **3.M2**, since its formalisation is specific to the third species.

SP3_U2 (REMOVED)

Third note of the penultimate measure must be below the fourth one.
This rule applies to all third species counterpoints.

$$M[2, m-2] > 0 \tag{6.4}$$

This rule lacks an independent musical foundation; it appears to be an observational byproduct of other cadence-related constraints. Moreover, it does not hold when the third-species voice is in the bass. Even acknowledging that exception, the figure 185 still derogates the rule. Consequently, I removed **SP3_U2** from the implementation.

SP3_U3 (3.M3)

The second note of the penultimate measure must be more than a semitone away from the fourth note.
This rule applies to all third-species counterpoints.

$$M_{brut}[1, m-2] + M_{brut}[2, m-2] > 1 \tag{6.5}$$

This is primarily a convenience rule, intended to prevent the introduction of chromatic motion in the penultimate measure—a situation that should already be avoided by other rules. Nevertheless, since it has no negative impact, it has been retained in the present work and named **3.M3**.

SP4_U2 (REMOVED)

No chromatic motion between 3 consecutive notes.
This rule applies to all fourth species counterpoints.

$$\begin{gathered}\rho := \text{any note position} \\ [(M_{brut}[\rho+1] = +1 \implies M^2_{brut}[\rho] \neq +2) \\ \wedge \\ (M_{brut}[\rho+1] = -1 \implies M^2_{brut}[\rho] \neq -2)]\end{gathered} \tag{6.6}$$

At first glance, this rule seems intended to avoid monotony and encourage melodic variety. However, in fourth species the notes are grouped by pairs (thesis–arsis), which means the melodic interval between the arsis and the thesis of the same pair is always 0. As a result, the rule could only be meaningfully applied to the intervals between successive arsis notes.

Because there is no explicit trace of this rule in the theoretical sources, I decided to remove it from the implementation.

SP5_P4 (REMOVED)

In a sequence of musical intervals, if an interval is skipped (disjoint degree), the motion between the current and next interval must be contrary.
This rule applies to all fifth species counterpoints.

$$\begin{gathered}\rho := \text{any note position} \\ M[\rho] > 2 \implies P[\rho] = 0\end{gathered} \tag{6.7}$$

In the code, this rule is commented as "marcel's rule." We may therefore assume that it originates from the treatise of Noël Gallon and Marcel Bitsch. The closest formulation we could find is the following:

> "26 - Disjoint movement at the bar line.
> Disjoint movement should be avoided, particularly when moving from one bar to another, especially in quarter notes.
> Tolerance:
> At the bar line, disjoint intervals preceded by contrary motion are acceptable"[2] [9, p.18].

However, this is not a rule but a tolerance and explicitly concerns only motion at the barline, whereas the implementation in our solver generalises it to all positions. Such a generalisation is too strict for Fux's style, and for this reason the rule has been removed from the formalisation.

A commented-out version of this rule exists in the file `ThirdSpeciesCounterpoint.cpp`, but it has never been activated in the implementation.

[2] Translated from French

SP5_H3 (REMOVED)

In fifth-species counterpoint, the thesis note of the penultimate measure must not be consonant with the cantus firmus if it belongs to the fourth species (half note tied to form a syncopation).
This rule applies to all fifth-species counterpoints.

$$S[m-2,0] = 4 \implies H[m-2,0] \notin Cons \tag{6.8}$$

In the tested examples, this rule is never violated. However, an exception could occur if there are two distinct harmonies in the penultimate measure. For this reason, I decided to disable this rule in the current implementation.

SP5_M2 (5.M1)

No unison between two consecutive notes.

$$\begin{gathered} \forall j \in [0, m-2], \\ N[0,j] \neq N[1,j], \\ N[2,j] \neq N[3,j] \end{gathered} \tag{6.9}$$

In its original form, this rule checks only that, within each measure, the first and second notes are not in unison, and the third and fourth notes are not in unison.

While musically logical—helping to avoid monotony and encouraging melodic movement—this application is overly narrow. Ideally, unisons should be avoided between *any* pair of consecutive notes, not just between the first–second and third–fourth notes of each measure.

I therefore changed the implementation, leading to the following formalization:

$$\begin{gathered} \forall j \in [0, m-2], \\ N[0,j] \neq N[1,j], \\ N[1,j] \neq N[2,j], \\ N[2,j] \neq N[3,j] \\ N[3,j] \neq N[0,j+1] \end{gathered} \tag{6.10}$$

In the present work, this rule is retained and renamed **5.M1**.

SP5_M3 (REMOVED)

No more than minor sixth interval between arsis and thesis notes
This rule applies to all fifth species counterpoints.

$$\begin{gathered} \forall j \in [0, m-2] \\ H[2,j] - H[0,j] \notin \{9, 10, 11\} \end{gathered} \tag{6.11}$$

Like rule SP3_U1 (renamed in **3.M2**), this rule essentially mirrors **1.M2**, but in the context of the fifth species. Its theoretical justification is therefore the same as the one provided in the explanation of SP3_U1.

However, in this formalization the condition is expressed specifically as the interval between the arsis and the thesis of the same measure, whereas the original formulation applies more generally to any pair of consecutive notes. Since the rule is never derogated in practice, I have currently disabled it. Nevertheless, it could be reintroduced in the future, either with an explicit justification or by reformulating it in the same generalized way as the updated rule **3.M2**.

SP5_M4 (5.M2)

For each measure from the second to the second-to-last, if a note is part of the fourth species and the corresponding subsequent note is constrained, then these two notes must not be the same.
This rule applies to all fifth species counterpoints.

$$\begin{gathered} \forall j \in [1, m-2] \\ (S[0,j] = 4 \land N[2,j] \neq -1) \implies N[0,j] \neq N[2,j] \end{gathered} \tag{6.12}$$

The original formulation of this rule arose directly from the implementation. In code, the notion of a "constrained note" referred to an auxiliary array indicating, for each beat, whether a note was imposed by a given species. However, in practice a note was marked as "not constrained" only if no note existed at that beat. This definition was problematic in the context of the fifth species, since an arsis note must always be present.

In the implementation, this rule was labelled "no same syncopation". It seems intended to enforce melodic variety and avoid repetition in a manner similar to rule **4.M2** for the fourth species. However, unlike the fourth species, the fifth species allows quarter notes at the arsis beat, which are not covered by the original condition.

To correct this, I reformulated the rule as follows: *For each measure from the second to the second-to-last, if both the thesis and the arsis belong to the fourth species (i.e., tied half notes forming a syncopation), then these two notes must not be the same.*

$$\begin{gathered} \forall j \in [1, m-2] \\ (S[0,j] = 4 \land S[2,j] = 4) \implies N[0,j] \neq N[2,j] \end{gathered} \tag{6.13}$$

With this correction, no tested figure derogates the rule. Nevertheless, since rule **4.M2** is treated as a stylistic preference rather than a strict prohibition, it would be more consistent in future versions to reclassify this fifth-species analogue as a preference as well.

For the moment, however, the rule is included in the complete model set under the designation **5.M2**.

SP5_P3 (REMOVED)

If the third note of a measure forms a unison with the cantus firmus, and the cantus firmus is not the lowest voice, and the first note of the next measure is fourth species, then the harmonic interval at the start of the next measure must not be a minor or major second.
This rule applies to all fifth species counterpoints.

$$\begin{aligned} &species(p) = 5 \quad \forall j \in [0, m-2] \\ &H(p, cf)[2, j] = 0 \wedge \neg A(cf)[j] \wedge S(p)[0, j+1] = 4 \\ &\implies H(p)[0, j+1] \in \{1, 2\} \end{aligned} \tag{6.14}$$

This rule aims to prevent weak harmonic progressions after a unison, ensuring stronger voice leading in fifth species counterpoint. However, it is long, complex, and lacks a solid musical foundation. For these reasons, it has been removed from the implementation.

6.3 Derogated Rules

This section examines the rules that are not respected by the solver when tested on Fux's examples. For each derogated rule, we provide both a musical explanation of the rule and a discussion of why it fails in specific cases. To facilitate the connection between the theoretical rule and its implementation in the code, each subsection is titled using the name of the rule, followed by the different function or file names where the rule is invoked in the program. This naming convention ensures clarity and traceability between the formal definition and its practical application, helping to identify potential sources of misimplementation or oversights.

1.H1 (CF_1H1, SP1_1H1 and SP5_H4)

All notes on the downbeat are consonant with the notes (on the downbeat) of the lowest stratum.
This rule applies to all configurations.

$$\begin{aligned} &\forall j \in [0, m-1] \\ &H[0, j] \in Cons \end{aligned} \tag{6.15}$$

This rule is only violated in cases involving ligatures. In the second species, for instance, Fux occasionally uses a syncopation in the penultimate measure, which technically contradicts the rule. He briefly justifies this exception with the explanation:

> "[...] in the measures with the ligatures, either a bad unison or an empty sounding octave would have resulted from using plain half notes" [8, p.87-88].

This specific case occurs in figures 126, 127, and 128. A more precise justification is offered by Gallon and Bitsch, in their rule 17 for the second species:

> "The superior delay of the leading note in syncopated half notes is admitted in the penultimate measure for the variety of endings"[3] [9, p.15].

At present, syncopation in the second species at the penultimate measure is not supported by our solver. For this reason, figures 126, 127, and 128 were tested using two half notes instead of syncopation which explains the observed violations of the rule in those figures. Implementing this exception would be a useful improvement for future work.

This rule is also violated in figures 151 and 156 because a diminished fifth occurs in the penultimate measure. This exception is explained by Gallon and Bitsch in their rule 55:

> "Tolerance: From four voices onwards, a diminished fifth between the bass and an upper part is permitted, in the penultimate measure only, when the leading tone is delayed in the bass."[3] [9, p.30]

Interestingly, Fux applies this tolerance in three-voice compositions as well. This rule should therefore be explicitly added to the solver.

The other figures that derogated this rule (listed in the table of the previous chapter) now respect it thanks to the delayed note handling explained in the Stratum Implementation section.

1.H5 (V2_1H5, V3_1H5)

The voices cannot play the same note at the same time except in the first and last measure.
This rule applies for thesis notes to all species in two and three voices.

$$\forall p_1, p_2 \in \{cf, cp_1, cp_2\} \text{ with } p_1 \neq p_2 \quad \forall i \in \{0,1,2,3\} \quad \forall j \in [1, m-2] \\ N(p_1)[i,j] \neq N(p_2)[i,j] \tag{6.16}$$

In the previous formalization, this rule was incorrectly implemented so that no voice could play the same note (unison) as another at any beat. This is not the correct interpretation. The rule was introduced by T. Wafflar, who justified it with the statement from the Fux's treatise:

> "[...] it should never be used except at the beginning and end"[4] referring to the unison [4, p.62]

[3] Translated from French
[4] Translated from French

. However, Fux was specifically referring to the first species. Gallon and Bitsch clarify the rule in their rule 53 as follows:

> "Unison may be used on the weak beat or on the weak part of the beat. Unison is permitted on the strong beat in the first and last measures only.
> Tolerance: For five or more voices, unison is permitted on the strong beat during an exercise." [9, p.29]

Based on this, the rule should only be enforced on the first beat. With this correction, no figures currently derogate the rule. The formalization is now:

$$\begin{gathered}\forall p_1, p_2 \in \{cf, cp_1, cp_2\} \text{ with } p_1 \neq p_2 \quad \forall j \in [1, m-2] \\ N(p_1)[0, j] \neq N(p_2)[0, j]\end{gathered} \tag{6.17}$$

Moreover, although Gallon and Bitsch states that the rule can be relaxed for five voices, Fux already derogates it in a four-voice example (figure 166, second measure, between the second and third voices). For this reason, the rule is applied only in two- and three-voice compositions.

1.H7 (CF_1H7_2V, CF_1H7_3V, SP1_1H7_2V, SP1_1H7_3V, SP3_1H7_3V, SP3_1H7_4V)

1.H7 *In two voice composition, the harmonic interval of the penultimate note must be a major sixth or a minor third depending on whether or not the cantus firmus is the lowest stratum. In three voice composition, that harmonic interval must be either a minor third, a perfect fifth, a major sixth or an octave.*
This rule applies to all species.

`2V:`

$$\begin{gathered}\rho := max(positions(m)) - 1 \\ H[\rho] = \begin{cases} 9 & if\ A(cf)[0, m-2] \\ 3 & \text{other} \end{cases}\end{gathered} \tag{6.18}$$

`3V:`

$$H[0, m-2] \in \{0, 3, 7, 9\} \tag{6.19}$$

Although the statement of rule 1.H7 specifies that it applies to all configurations of two- and three-voice counterpoint, the implementation did not cover every case. Specifically:

- In two-voice counterpoint, the rule was not applied to the second, third, fourth, or fifth species.
- In three-voice counterpoint, it was not applied to the second, fourth, or fifth species.

The reason lies in the inheritance structure of the code: the rule was implemented only in the two-voice and three-voice constructors of the `FirstSpeciesCounterpoint` class, and in the three-voice constructor of the `ThirdSpeciesCounterpoint` class. Since the classes for the other species only call the generic constructor of the parent class, the specific constructors where 1.H7 is implemented were never invoked. As a result, the rule was never triggered in many derived species configurations. In future work, the implementation should be modified so that the constraint is called directly in `TwoVoiceCounterpoint.cpp` and `ThreeVoiceCounterpoint.cpp`, ensuring that it is enforced for all species.

A second issue came from the way harmonic intervals were computed in the previous implementation. Rule 1.H7 requires the harmonic interval of the penultimate note of the upper voice(s). However, harmonic intervals were always calculated against the first note of the lowest stratum in each measure. This caused errors whenever the lowest voice contained more than one note per measure (e.g., second or third species in the bass). For example, if the cantus firmus was the upper voice and the lower voice was in the third species, the intended interval is that between the final note of the cantus firmus in the penultimate measure and the final note of the lower voice in the same measure. Instead, the old implementation incorrectly measured it against the first note of the lower voice in that measure. With the new Strata implementation (see section 6.1), each beat is assigned to the note actually sounding, which allows the correct interval to be computed.

In the current implementation, two main reasons explain why some figures derogate the rule. First, Figures 56, 109, 110, 111, 113, 114, 115, 116, 118, 119, 125, and 132 use a major third instead of a minor third or major sixth. There is no strong reason to reject the major third when it belongs to the mode of the counterpoint. As Gallon and Bitsch note:

> "The penultimate measure may be harmonized, in both major and minor keys" [9, p.59].

The major third is therefore now authorized in the implementation, leading to the following formalisation:

`2V:`

$$\rho := \max(positions(m)) - 1$$

$$H[\rho] = \begin{cases} 9 & if\ A(cf)[0, m-2] \\ 3 \vee 4 & \text{otherwise} \end{cases} \tag{6.20}$$

`3V:`

$$H[0, m-2] \in \{0, 3, 4, 7, 9\} \tag{6.21}$$

Second, in Figures 151 and 156, when a fourth-species counterpoint appears in the lowest stratum, a diminished fifth occurs in the penultimate measure. This case is explicitly covered by a tolerance described by Gallon and Bitsch:

> "From four voices onward, a diminished fifth is permitted between the bass and an upper part, but only in the penultimate measure, when the leading tone is delayed in the bass"[5] [9, p.30, rule 54].

Fux himself applies this tolerance to three-voice compositions as well. This exception has not yet been implemented in the solver but should be considered in future work.

1.H8 (V3_1H8, V4_1H8)

The harmonic triad should be used as much as possible, and in four voices it should be used in its natural order with the octave if possible.
This rule applies to all thesis chords in three and four part composition, in all species.

This rule is implemented as a preference. For 4 voices, the cots depend of the case. We will start with the worst case (not using the harmonic triad) and work our way up to the best case (using the harmonic triad in its natural order, with the octave). By "natural order", Fux refers to the order given by the harmonic series [8, p.161]. We have the lower note then a fifth, an octave, and a third which is in fact a tenth. These are the second, third, fourth and fifth harmonics, respectively.

`3V:`

$$\begin{gathered}\forall j \in [0, m-1] \\ (H(b)[0,j] \notin 3,4) \vee (H(c)[0,j] \neq 7) \iff C_{prefer\_harmonic\_triad}[j] = 1\end{gathered} \tag{6.22}$$

`4V:`

`Worst case:` Not using the harmonic triad : either there is no third or fifth, or there is a note that does not belong to the harmonic triad.

$$\begin{aligned}&\forall j \in [0, m-1] \\ &(\forall h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \{3,4\})) \\ &\vee \ (\forall h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \{7\})) \\ &\vee \ \big(\exists h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \text{Cons}_{\text{h-triad}})\big) \\ &\implies C_{prefer\_harmonic\_triad}[j] = not\_harmonic\_triad\_cost\end{aligned} \tag{6.23}$$

`Better:` no octave, doubling the fifth.

[5] Translated from French

$$\forall j \in [0, m-1]$$
$$\left(\sum_{h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\}} \mathbf{1}_{h=7} = 2 \right) \Longrightarrow C_{prefer\_harmonic\_triad}[j] = double\_fifth\_cost \tag{6.24}$$

`Better yet:` no octave, doubling the third. In this case, we must also check that the two thirds are of the same nature (minor or major).

$$\begin{gathered}\forall j \in [0, m-1] \\ \left(\sum_{h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\}} \mathbf{1}_{h \in \{3,4\}} = 2 \right) \Longrightarrow (C_{prefer\_harmonic\_triad}[j] = double\_thirds\_cost) \\ (H_b[0,j] \in \{3,4\} \wedge H_c[0,j] \in \{3,4\}) \Longrightarrow (H_b[0,j] = H_c[0,j]) \\ (H_b[0,j] \in \{3,4\} \wedge H_d[0,j] \in \{3,4\}) \Longrightarrow (H_b[0,j] = H_d[0,j]) \\ (H_c[0,j] \in \{3,4\} \wedge H_d[0,j] \in \{3,4\}) \Longrightarrow (H_c[0,j] = H_d[0,j])\end{gathered} \tag{6.25}$$

`Even better:` octave used, but not in the natural order.

$$\begin{gathered}\forall j \in [0, m-1] \\ (H_b[0,j] = 7) \wedge (H_c[0,j] \in \{3,4\}) \wedge (H_d[0,j] = 0) \\ \quad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\ (H_b[0,j] \in \{3,4\}) \wedge (H_c[0,j] = 0) \wedge (H_d[0,j] = 7) \\ \quad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\ (H_b[0,j] \in \{3,4\}) \wedge (H_c[0,j] = 7) \wedge (H_d[0,j] = 0) \\ \quad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\ (H_b[0,j] = 0) \wedge (H_c[0,j] \in \{3,4\}) \wedge (H_d[0,j] = 7) \\ \quad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\ (H_b[0,j] = 0) \wedge (H_c[0,j] = 7) \wedge (H_d[0,j] \in \{3,4\}) \\ \quad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost\end{gathered} \tag{6.26}$$

`Best:` Harmonic triad with the octave, in natural order.

$$\begin{gathered}\forall j \in [0, m-1] \\ (H_b[j] = 7) \wedge (H_c[j] = 0) \wedge (H_d[j] \in \{3,4\}) \Longleftrightarrow C_{\text{prefer-harmonic-triad}}[j] = 0\end{gathered} \tag{6.27}$$

This rule is derogated only for 4 voices counterpoint.

Each voice is associated with an array of values representing the costs linked to harmonic intervals at each note position. However, in four-voice compositions, a problem arises: multiple costs can be assigned to the same variable, which is not permitted and leads to an error during execution. For example, a chord might include both a note outside the harmonic triad and two minor thirds, raising the question: which cost should be assigned to this chord - *not_harmonic_triad_cost* or *double_thirds_cost*? (see, for instance, figure 169, measure 2). To resolve this issue, I modified the formalization and the code to introduce a conditional check for cases involving doubling of fifths or thirds. Specifically, the cost is only applied if no more severe violation has already been detected, ensuring that only the most critical cost is assigned when multiple rule violations overlap.

Here is the new Formalization for `Better` and `Better yet` cases:

`Better:` no octave, doubling the fifth.

$$\begin{gathered}\forall j \in [0, m-1] \\ \left(\begin{array}{l}\left(\displaystyle\sum_{h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\}} \mathbf{1}_{h=7} = 2\right) \\ \wedge \neg(\forall h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \{3,4\})) \\ \wedge \neg\big(\exists h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \text{Cons}_{\text{h-triad}})\big)\end{array}\right) \\ \implies C_{prefer\_harmonic\_triad}[j] = double\_fifth\_cost\end{gathered} \tag{6.28}$$

`Better yet:` no octave, doubling the third. In this case, we must also check that the two thirds are of the same nature (minor or major).

$$\begin{gathered}\forall j \in [0, m-1] \\ \left(\begin{array}{l}\left(\displaystyle\sum_{h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\}} \mathbf{1}_{h \in \{3,4\}} = 2\right) \\ \wedge \neg(\forall h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \{7\})) \\ \wedge \neg\big(\exists h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \text{Cons}_{\text{h-triad}})\big)\end{array}\right) \\ \implies (C_{prefer\_harmonic\_triad}[j] = double\_thirds\_cost) \\ (H_b[0,j] \in \{3,4\} \wedge H_c[0,j] \in \{3,4\}) \implies (H_b[0,j] = H_c[0,j]) \\ (H_b[0,j] \in \{3,4\} \wedge H_d[0,j] \in \{3,4\}) \implies (H_b[0,j] = H_d[0,j]) \\ (H_c[0,j] \in \{3,4\} \wedge H_d[0,j] \in \{3,4\}) \implies (H_c[0,j] = H_d[0,j])\end{gathered} \tag{6.29}$$

Here is the previous code:

```
1    void H8_4v_preferHarmonicTriad(Home home, IntVarArray triadCostArray, Stratum
       ↪  * upper1, Stratum* upper2, Stratum* upper3){
```

```
        for(int i = 0; i < triadCostArray.size(); i++){

            IntVar H_b = upper1->getHInterval()[i*4];
            IntVar H_c = upper2->getHInterval()[i*4];
            IntVar H_d = upper3->getHInterval()[i*4];

            BoolVar H_b_is_third    = expr(home, H_b==MINOR_THIRD || H_b==MAJOR_THIRD);
            BoolVar H_b_is_fifth    = expr(home, H_b==PERFECT_FIFTH);
            BoolVar H_b_is_octave   = expr(home, H_b==UNISSON);

            BoolVar H_c_is_third    = expr(home, H_c==MINOR_THIRD || H_c==MAJOR_THIRD);
            BoolVar H_c_is_fifth    = expr(home, H_c==PERFECT_FIFTH);
            BoolVar H_c_is_octave   = expr(home, H_c==UNISSON);

            BoolVar H_d_is_third    = expr(home, H_d==MINOR_THIRD || H_d==MAJOR_THIRD);
            BoolVar H_d_is_fifth    = expr(home, H_d==PERFECT_FIFTH);
            BoolVar H_d_is_octave   = expr(home, H_d==UNISSON);

            // worst case : not a harmonic triad with at least a third and a fifth
            BoolVar no_fifth_or_no_third = expr(home, H_b_is_third + H_c_is_third + H_d_is_third == 0 || H_b_is_fifth + H_c_is_fifth + H_d_is_fifth == 0);
            BoolVar note_outside_harmonic_triad = expr(home, H_b_is_third + H_b_is_fifth + H_b_is_octave == 0 || H_c_is_third + H_c_is_fifth + H_c_is_octave == 0 || H_d_is_third + H_d_is_fifth + H_d_is_octave == 0);

            rel(home, (note_outside_harmonic_triad || no_fifth_or_no_third) >> (triadCostArray[i] == not_harmonic_triad_cost));

            // now we are left with only combinations with at a third, a fifth, and another note of the harmonic triad.
            // Doubling the fifth
            rel(home, expr(home, H_b_is_fifth + H_c_is_fifth + H_d_is_fifth == 2) >> (triadCostArray[i] == double_fifths_cost));

            // Doubling the third, and ensure it is the same type of third (not a major and a minor)
            rel(home, expr(home, H_b_is_third + H_c_is_third + H_d_is_third == 2) >> (triadCostArray[i] == double_thirds_cost));
            rel(home, (H_b_is_third && H_c_is_third) >> (H_b == H_c));
            rel(home, (H_b_is_third && H_d_is_third) >> (H_b == H_d));
            rel(home, (H_c_is_third && H_d_is_third) >> (H_c == H_d));

            // triad with octave
            rel(home, (H_b_is_fifth && H_c_is_third && H_d_is_octave) >> (triadCostArray[i] == triad_with_octave_cost)); // 5 3 8
            rel(home, (H_b_is_third && H_c_is_octave && H_d_is_fifth) >> (triadCostArray[i] == triad_with_octave_cost)); // 3 8 5
            rel(home, (H_b_is_third && H_c_is_fifth && H_d_is_octave) >> (triadCostArray[i] == triad_with_octave_cost)); // 3 5 8
            rel(home, (H_b_is_octave && H_c_is_third && H_d_is_fifth) >> (triadCostArray[i] == triad_with_octave_cost)); // 8 3 5
            rel(home, (H_b_is_octave && H_c_is_fifth && H_d_is_third) >> (triadCostArray[i] == triad_with_octave_cost)); // 8 5 3

            // Best case : 5 8 3
            rel(home, (H_b_is_fifth && H_c_is_octave && H_d_is_third) >> (triadCostArray[i] == 0));

        }
    }
```

Listing 6.1: Previous implementation of 1.H8 for four voices configuration

In which I modified line 30 in the previous frame to become:

```
1     rel(home, expr(home, (H_b_is_fifth + H_c_is_fifth + H_d_is_fifth == 2) && !
        ↪  note_outside_harmonic_triad && !no_fifth_or_no_third) >> (
        ↪  triadCostArray[i] == double_fifths_cost));
```

Listing 6.2: Modification of double fifths case in 1.H8 implementation for four voices configuration

And line 33:

```
1     rel(home, expr(home, (H_b_is_third + H_c_is_third + H_d_is_third == 2) && !
        ↪  note_outside_harmonic_triad && !no_fifth_or_no_third) >> (
        ↪  triadCostArray[i] == double_thirds_cost));
```

Listing 6.3: Modification of double thirds case in 1.H8 implementation for four voices configuration

1.H10 (STRATUM_1H10_UPPER)

In three voice composition, tenths are prohibited in the last chord.
This rule applies to all species in three voices.

$$H_{brut}[0, m-1] > 12 \implies H[0, m-1] \notin \{3, 4\}$$

Fux remarks:

> "One feels that the degree of perfection and repose which is required of the final chord does not become sufficiently positive with this imperfect consonance" speaking about a tenth [8, p.77].

He then advises:

> "Therefore, it is advisable to omit the third altogether" referring to the final measure [8, p.80].

However, he later nuances this directive by adding:

> "What I told you regarding the omission of the third holds true only in cases in which it is possible"[8, p.82]

This indicates that the rule is not absolute and may be disregarded in certain contexts, making it a good candidate to be reformulated as a preference with an associated cost in the solver.

As already said in the section 6.2 about the rule 1.H12, Fux consistently favors the major third for the final chord, regardless of the mode of the counterpoint which is not the case of the some other composers.

In the present work, this rule has been disabled in its strict form but could be reintroduced as a soft preference, thereby leaving the final choice to the composer. However, since Fux himself does not always respect this rule (e.g., figure 112), I ultimately decided to suspend it.

1.H13 (V4_U2)

For every pair of upper voices, the thesis note of each measure must never form a minor second interval.
This rule applies to all species in three- and four-voice counterpoint.

The unknown rule **V4_U2** was already introduced in section 6.2, where its formalization is presented.

In the previous implementation, apparent violations of this rule occurred because delayed notes were not handled correctly. The implementation has now been updated to use the revised *Stratum* framework. As a result, the rule is now enforced consistently without spurious violations.

2.H2 (SP2_2H2)

Arsis harmonies cannot be dissonant, except in the case of a diminution.
This rule applies to second-species counterpoints for all numbers of voices.

$$\forall j \in [0, m-1], \forall p : \text{species}(p) = 2$$

$$IsDim(p)[j] = \begin{cases} \top & \text{if } M^2(p)[0,j] \in \{3,4\} \wedge M^1(p)[0,j] \in \{1,2\} \wedge M^1(p)[2,j] \in \{1,2\} \\ \bot & \text{otherwise} \end{cases}$$

$$\forall j \in [0, m-1] \quad \neg IsCons(p)[2,j] \implies IsDim(p)[j]$$

In the updated implementation, this rule is no longer violated. When the second species is in an upper voice, past violations were due to incorrect handling of delayed notes—a problem now resolved through the improved *Stratum* mechanism.

2.H3 (SP2_2H3_2V, SP2_2H3_3V, SP2_2H3_4V)

When composing in two voices, in the penultimate measure the harmonic interval of perfect fifth must be used for the thesis note if possible. Otherwise, a sixth interval should be used instead.
This rule applies to all two voice configurations in which the counterpoint is of the second species.

$$H[0, m-2] \in \{0, 7, 8, 9\}$$

$$\text{penulthesis}_{cost} = \begin{cases} \text{cost}_{\text{penulthesis}} & \text{if } H[0, m-2] \neq 7 \\ 0 & \text{otherwise} \end{cases}$$

In its textual explanation, the rule is stated as applying only to two-voice counterpoint. However, in the previous implementation, it was applied to all configurations, regardless of the number of voices. This inconsistency has been corrected by removing the constraint for counterpoint with more than two voices.

3.H1 (SP3_3H1)

If five notes follow each other by joint degrees in the same direction, then the harmonic interval of the third note must be consonant
This rule applies in all configurations, to third species counterpoints.

$$\forall j \in [0, m-1]$$
$$\left(\bigwedge_{i=0}^{3} M[i,j] \leq 2\right) \wedge \left(\left(\bigwedge_{i=0}^{3} M_{brut}[i,j] > 0\right) \vee \left(\bigwedge_{i=0}^{3} M_{brut}[i,j] < 0\right)\right)$$
$$\implies IsCons[2,j]$$

The current implementation of this rule is overly strict. Immediately after introducing it, Fux specifies an important exception:

> "This does not hold if, firstly, the second and the fourth notes are consonant, in which case the third note may be dissonant." [Mann, p. 50]

This exception is not currently handled in the model, which results in the rule being applied in situations where Fux would have allowed a violation. For this reason, the rule has been disabled in the present version. It should be revised to incorporate Fux's stated exception before being reintroduced into the solver.

3.H2 (SP3_3H2)

If the third harmonic interval of a measure is dissonant then the second and the fourth interval must be consonant and the third note must be a diminution
This rule applies in all configurations, to third species counterpoints.

$$\forall j \in [0, m-1]$$
$$IsCons[2, j] \vee (IsCons[1, j] \wedge IsCons[3, j] \wedge IsDim[j])$$
where $IsDim[j] = \top$ when the 3^{rd} note of the measure j is a diminution.

It translates a very important concept in counterpoint (which was already present in the second species) : all dissonances are surrounded by consonances. But this rule shouldn't be applied to the penultimate measure where the second and the third can be dissonant with the first and the fourth consonant. The formalization is slightly modified to become:

$$\forall j \in [0, m-3]$$
$$IsCons[2, j] \vee (IsCons[1, j] \wedge IsCons[3, j] \wedge IsDim[j])$$
where $IsDim[j] = \top$ when the 3^{rd} note of the measure j is a dimension. (6.30)

3.H4 (SP3_3H4)

In two voice composition, in the penultimate measure, if the counterpoint is the lowest stratum, then the harmonic interval of the first note should be a minor third. This rule applies in two voices when the counterpoint is of the third species.

$$A(cp)[m-2] \implies H[0, m-2] = 3$$

In the previous implementation, this rule was placed in `ThirdSpeciesCounterpoint.cpp`, even though it is a harmonic constraint that should be applied to the *cantus firmus*. Since the harmonic interval is computed from the lowest voice (here, the third-species voice), the rule needed to be moved. I removed the original implementation from `ThirdSpeciesCounterpoint.cpp` and created a new version in `TwoVoiceCounterpoint.cpp` that check that the part is a third species counterpoint to correctly compute the harmonic interval from the cantus firmus and ensure the rule only applies to two-voice counterpoint.

The rule remains violated in Figure 58. Nevertheless, the constraint is musically coherent and has therefore been retained in the implementation. Although it could be reconsidered as a preference in the future, in my view it should remain a strict rule.

1.P6 (V3_1P6, V4_1P6)

It is prohibited that all parts move in the same direction.
This rule applies to all configurations in three or four voices.

$$\forall j \in [0, m-1] : \bigvee_{p \in \{cf, cp_1, cp_2, cp_3\}} P(p)[0, j] \in \{0, 1\}$$

In the previous version of the code, the same implementation of the rule was used for both three- and four-voice configurations. As a result, when the rule was called in four-voice counterpoint, it only checked the motion of three voices instead of all four. To correct this, I created a dedicated version of the rule for four voices, which is now called whenever the configuration involves four voices.

During testing, I also discovered that the melodic interval of the lowest stratum was incorrectly computed in Figure 173. This error caused the solver to report a derogation of the rule. The issue was traced to the fact that the melodic interval of the lowest stratum wasn't well calculated. I fixed this bug, and with the correction, the rule is now applied correctly.

2.P1 (SP2_2P1_2V, SP2_2P1_3V)

If the melodic interval of the counterpoint between the thesis and the arsis is larger than a third, then the motion is perceived based on the arsis note.
This rule applies to all counterpoints of the second species.

Note: This rule is used to evaluate all other motion rules in the context of second-species counterpoint. The special case of the battuta octave (rule 1.P3) always perceives motion from the last note of the previous measure, but this is already explicitly formulated in its definition. As such, it does not affect this rule and requires no reformulation.

$$\forall j \in [0, m-1]$$
$$P_{real}[j] = \begin{cases} P[2, j] & \text{if } M[0, j] > 4 \\ P[0, j] & \text{otherwise} \end{cases}$$

In the code, this constraint redefined rule **1.P1** in order to correctly account for motion in the second species. In other words, when the leap from the thesis to the arsis exceeds a third, the harmonic evaluation is based on the arsis rather than the thesis, so as to prevent approaching a perfect consonance by direct motion.

However, the original implementation did not correctly reflect this principle: motion was mistakenly computed from *arsis to arsis*, whereas the correct computation must be from *arsis to thesis*. I corrected this error, and the rule is no longer derogated in the tested figures.

For clarity, I slightly reformulated the statement of the rule in the complete set of rules as follows: *"If the melodic interval of the counterpoint between the thesis and the arsis is larger than a third, then the motion is perceived based on the arsis note to the next thesis note."*

4.P1 (SP4_4P1, SP5_4P1)

Dissonant harmonies must be followed by the next lower consonant harmony.
This rule applies in all configurations to fourth species counterpoints.

$$\begin{gathered} \forall j \in [1, m-1] \\ \neg isCons[0, j] \implies M_{brut}[0, j] \in \{1, 2\} \end{gathered} \tag{6.31}$$

In the implementation, this rule was also applied in the fifth species, even though this was not explicitly stated in the original description. Nevertheless, the extension to the fifth species proved both logically consistent and error-free, since it applies naturally to tied half notes that create syncopation. For the fifth species, however, the mathematical formalisation differs slightly, as the rule must only be applied when the note is part of a fourth-species pattern (tied half notes):

$$\begin{gathered} \forall j \in [1, m-1] \\ \neg isCons[0, j] \wedge S[0, j] = 4 \implies M^2_{brut}[0, j] \in \{1, 2\} \end{gathered} \tag{6.32}$$

The use of M^2 is justified because, in the fifth species, every beat can potentially contain a note. In this case, it is necessary to check the melodic interval specifically between the thesis and the arsis note.

In the previous implementation, this constraint was not applied correctly for fourth-species counterpoint due to an incorrect index being used for the melodic interval. Even after correcting this index, the rule continued to be derogated whenever the fourth-species voice appeared in the lowest stratum. This was because harmonic intervals in fourth species were computed from the arsis (resolution) rather than the thesis (suspension), which incorrectly classified many thesis notes as dissonant.

This problem has now been resolved with the new *Strata* implementation, which assigns each beat to the note that carries the actual harmonic weight. By correctly handling delayed notes, harmonic intervals are now computed consistently, and the rule is enforced properly in both fourth- and fifth-species counterpoint.

4.P5 (SP4_4P5_3V, SP4_4P5_4V)

In three and four part composition, stationary movement in the bass implies dissonance in the fourth species part.
This rule applies to all fourth species counterpoints in three or four voice configurations.

$$\forall j \in [0, m-1] :$$
$$M(a)[0, j] \neq 0 \Leftrightarrow H[2, j] \in Cons$$
$$M(a)[0, j] = 0 \Leftrightarrow H[2, j] \in Dis$$

In the previous thesis, this constraint was deactivated in the code with the comment: "after careful testing, Fux does not seem to follow this rule in many of his examples." My own analysis confirms this conclusion.

Evidence: In Figures 146 and 147 (measure 6), the bass line shows stationary motion, yet the arsis note of the fourth-species voice is consonant.

These examples demonstrate that Fux explicitly tolerates stationary motion in the bass while maintaining consonance in the fourth-species line, contrary to the stricter stance of some musicologists. As a result, this rule should not be treated as a hard constraint. Instead, it would be more appropriate to reformulate it as a preference, implemented as a soft constraint with an associated cost, so that the solver favours but does not strictly enforce this behaviour.

5.M2 (SP5_M4)

For each measure from the second to the second-to-last, if both the thesis and the arsis belong to the fourth species (i.e., tied half notes forming a syncopation), then these two notes must not be the same.

This rule has already been discussed in section 6.2, where both the problem and its resolution were detailed.

To summarise, the original implementation incorrectly relied on a "constrained note" array, which did not properly account for the arsis in the fifth species. I reformulated the rule to explicitly require that, in measures where both thesis and arsis are tied half notes, these notes must not be identical. With this correction, no tested figure derogates the rule. For the moment, the rule is retained in the complete model set under the designation **5.M2**, though it may be reconsidered as a stylistic preference in future work.

Chapter 7

Full Validated Model of Fux Counterpoint

This chapter presents the complete set of contrapuntal rules implemented in the solver. The content is based on the work of Lamotte (2024), Wafflard (2023), and Sprockeels (2022), revised and expanded by Cleenewerk & de Patoul (2024). The goal here is to provide a unified and consistent reference: rules have been reorganised, reformulated for clarity, and their scopes made explicit. In some cases, redundant or outdated rules from previous versions were removed, while others were refined to align more closely with the intended Fuxian style.

Each rule is identified by a unique code. The first number indicates the species concerned (0 = general rule, 1 = first species, etc.), the letter indicates the category (H = harmonic, M = melodic, P = motion, R = rhythmic), and the second number is the index of the rule within that category. When a rule applies to several species, the code reflects the main one but its scope is clarified in the text.

For a detailed explanation of these rules, their underlying logic, and their origin in *Gradus ad Parnassum*, the reader may refer to the corresponding theses: T. Wafflard for two-voice rules[18], A. Lamotte for three-voice rules[13] and L. Cleenewerk & D. de Patoul for four-voice rules[5].

7.1 General Rules (G)

The rules **G1** to **G3** do not have explicit mathematical formalizations, since they are not implemented as separate constraints but are instead embedded directly into the structure of the program itself. They apply universally, regardless of the number of voices or the species considered.

G1

Harmonic intervals are calculated from the lowest note.

G2

The number of measures of the counterpoints must be the same as the number of measures of the cantus firmus.

$$m_{\text{cp}} = m_{\text{cf}} \tag{7.1}$$

This guarantees structural alignment between the cantus firmus and the counterpoint.

G3

The counterpoints must have the same time signature and the same tempo as the cantus firmus.

G4

The counterpoints must be in the same key as the cantus firmus.

G5

The range of the counterpoints must be consistent with the instruments used.

This prevents writing notes that would be impractical or impossible to perform.

G6

Chromatic melodies are forbidden for two and three voice composition, and to be avoided for four voice composition.

`2V & 3V:`

$$\forall \rho \in positions(m-2) \quad \begin{cases} (M_{brut}[\rho] = 1 \wedge M_{brut}[\rho+1] = 1) \iff \bot \\ (M_{brut}[\rho] = -1 \wedge M_{brut}[\rho+1] = -1) \iff \bot \end{cases} \tag{7.2}$$

For four voices, the preference of not having chromatic melodies is already taken into account by the cost of using borrowed notes.

G7

Melodic intervals should be small.

$$\forall \rho \in positions(m-1)$$
$$M_{deg\_costs}[\rho] = \begin{cases} cost_{secondMdeg} & \text{if } M[\rho] \in \{0,1,2\} \\ cost_{thirdMdeg} & \text{if } M[\rho] \in \{3,4\} \\ cost_{fourthMdeg} & \text{if } M[\rho] = 5 \\ cost_{tritoneMdeg} & \text{if } M[\rho] = 6 \\ cost_{fifthMdeg} & \text{if } M[\rho] = 7 \\ cost_{sixthMdeg} & \text{if } M[\rho] \in \{8,9\} \\ cost_{seventhMdeg} & \text{if } M[\rho] \in \{10,11\} \\ cost_{octaveMdeg} & \text{if } M[\rho] = 12 \end{cases} \tag{7.3}$$

7.2 Constraints of the First Species

Harmonic Rules

1.H1

All notes on the downbeat are consonant with the notes (on the downbeat) of the lowest stratum.
This rule applies in all configurations.

$$\begin{gathered} \forall j \in [0, m-1] \\ H[0,j] \in Cons \end{gathered} \tag{7.4}$$

1.H2

In two voices, the first harmony must be a perfect consonance.
This rule applies to all species in two voices.

$$H[0,0] \in Consp \tag{7.5}$$

1.H3

In two voice composition, the last harmonic interval must be a perfect consonance. When composing for three or four voices, the last chord should be composed only of notes of the harmonic triad.
This rule applies in all configurations.

$$\begin{aligned} \texttt{2V:} \quad & H[0, m-1] \in Consp \\ \texttt{3V \& 4V:} \quad & \forall s \in \{b, c, d\}, \quad H[s, m-1] \in Consh_{\text{triad}} \end{aligned} \tag{7.6}$$

1.H4

The key tone is tuned according to the first note of the cantus firmus.
This rule applies in all configurations.

$$\begin{aligned} N(a)[0,0] \mod 12 &= N(cf)[0,0] \mod 12 \\ N(a)[0,m-1] \mod 12 &= N(cf)[0,0] \mod 12 \end{aligned} \tag{7.7}$$

1.H5

The voices cannot play the same note at the same time except in the first and last measure
This rule applies to thesis notes in all species with two and three voices.

$$\begin{gathered} \forall p_1, p_2 \in \{cf, cp_1, cp_2\} \text{ with } p_1 \neq p_2 \quad \forall i \in \{0,1,2,3\} \quad \forall j \in [1, m-2] \\ N(p_1)[i,j] \neq N(p_2)[i,j] \end{gathered} \tag{7.8}$$

1.H6

On thesis notes, imperfect consonances are preferred to perfect ones; fifths preferred to octaves.
This rule applies in all configurations.

$$\begin{gathered} \forall j \in [0, m-1] \\ Pconscosts[j] = \begin{cases} cost_{Pcons\_oct} & \text{if } H[0,j] = 0, \\ cost_{Pcons\_fifth} & \text{if } H[0,j] = 7, \\ 0 & \text{otherwise.} \end{cases} \end{gathered} \tag{7.9}$$

1.H7

In two voice composition, the harmonic interval of the penultimate note must be a major sixth or a third (minor or major) depending on whether or not the cantus firmus is the lowest stratum. In three voice composition, that harmonic interval must be either a minor third, a major third, a perfect fifth, a major sixth or an octave.
This rule applies to the penultimate *note* for all species with two and three voices

`2V:`

$$\rho := \max(positions(m)) - 1$$
$$H[\rho] = \begin{cases} 9 & if\ A(cf)[0, m-2] \\ 3 \vee 4 & \text{otherwise} \end{cases} \tag{7.10}$$

`3V:`

$$H[0, m-2] \in \{0, 3, 4, 7, 9\} \tag{7.11}$$

1.H8

The harmonic triad should be used as much as possible, and in four voices it should be used in its natural order with the octave if possible.
This rule applies to thesis chords for three and four voices composition.

`3V:`

$$\begin{gathered} \forall j \in [0, m-1] \\ (H(b)[0, j] \notin 3, 4) \vee (H(c)[0, j] \neq 7) \iff C_{prefer\_harmonic\_triad}[j] = 1 \end{gathered} \tag{7.12}$$

`4V:`

`Worst case:` Not using the harmonic triad : either there is no third or fifth, or there is a note that does not belong to the harmonic triad.

$$\begin{aligned} &\forall j \in [0, m-1] \\ &\big(\forall h \in \{H_b[0, j], H_c[0, j], H_d[0, j]\} \quad (h \notin \{3, 4\})\big) \\ &\vee\ \big(\forall h \in \{H_b[0, j], H_c[0, j], H_d[0, j]\} \quad (h \notin \{7\})\big) \\ &\vee\ \big(\exists h \in \{H_b[0, j], H_c[0, j], H_d[0, j]\} \quad (h \notin \text{Cons}_{\text{h-triad}})\big) \\ &\implies C_{prefer\_harmonic\_triad}[j] = not\_harmonic\_triad\_cost \end{aligned} \tag{7.13}$$

`Better:` no octave, doubling the fifth.

$$\begin{gathered} \forall j \in [0, m-1] \\ \left(\begin{aligned} &\left(\sum_{h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\}} \mathbf{1}_{h=7} = 2 \right) \\ &\wedge \neg(\forall h \in \{H_b[0, j], H_c[0, j], H_d[0, j]\} \quad (h \notin \{3, 4\})) \\ &\wedge \neg\big(\exists h \in \{H_b[0, j], H_c[0, j], H_d[0, j]\} \quad (h \notin \text{Cons}_{\text{h-triad}})\big) \end{aligned} \right) \\ \implies C_{prefer\_harmonic\_triad}[j] = double\_fifth\_cost \end{gathered} \tag{7.14}$$

`Better yet:` no octave, doubling the third. In this case, we must also check that the two thirds are of the same nature (minor or major).

$$
\begin{aligned}
&\forall j \in [0, m-1] \\
&\left(\begin{array}{l}
\left(\sum_{h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\}} \mathbf{1}_{h \in \{3,4\}} = 2\right) \\
\wedge \neg(\forall h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \{7\})) \\
\wedge \neg\big(\exists h \in \{H_b[0,j], H_c[0,j], H_d[0,j]\} \quad (h \notin \text{Cons}_{\text{h-triad}})\big)
\end{array}\right) \\
&\qquad \Longrightarrow (C_{prefer\_harmonic\_triad}[j] = double\_thirds\_cost) \\
&(H_b[0,j] \in \{3,4\} \wedge H_c[0,j] \in \{3,4\}) \Longrightarrow (H_b[0,j] = H_c[0,j]) \\
&(H_b[0,j] \in \{3,4\} \wedge H_d[0,j] \in \{3,4\}) \Longrightarrow (H_b[0,j] = H_d[0,j]) \\
&(H_c[0,j] \in \{3,4\} \wedge H_d[0,j] \in \{3,4\}) \Longrightarrow (H_c[0,j] = H_d[0,j])
\end{aligned}
\tag{7.15}
$$

`Even better:` octave used, but not in the natural order.

$$
\begin{aligned}
&\forall j \in [0, m-1] \\
&(H_b[0,j] = 7) \wedge (H_c[0,j] \in \{3,4\}) \wedge (H_d[0,j] = 0) \\
&\qquad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\
&(H_b[0,j] \in \{3,4\}) \wedge (H_c[0,j] = 0) \wedge (H_d[0,j] = 7) \\
&\qquad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\
&(H_b[0,j] \in \{3,4\}) \wedge (H_c[0,j] = 7) \wedge (H_d[0,j] = 0) \\
&\qquad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\
&(H_b[0,j] = 0) \wedge (H_c[0,j] \in \{3,4\}) \wedge (H_d[0,j] = 7) \\
&\qquad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost \\
&(H_b[0,j] = 0) \wedge (H_c[0,j] = 7) \wedge (H_d[0,j] \in \{3,4\}) \\
&\qquad \Longleftrightarrow (C_{prefer\_harmonic\_triad}[j] = triad\_with\_octave\_cost
\end{aligned}
\tag{7.16}
$$

`Best:` Harmonic triad with the octave, in natural order.

$$
\begin{aligned}
&\forall j \in [0, m-1] \\
&(H_b[j] = 7) \wedge (H_c[j] = 0) \wedge (H_d[j] \in \{3,4\}) \Longleftrightarrow C_{\text{prefer-harmonic-triad}}[j] = 0
\end{aligned}
\tag{7.17}
$$

1.H11

Octaves should be preferred over unisons.
This rule applies to all configurations.

This rule is taken into account by **1.H5** for two and three voices, and by **1.H8** for four voices.

1.H12

In three- and four-voice counterpoint, the final chord must not contain a minor third.
This rule applies to any species in three and four voice counterpoints.

$$H[0, m-1] \notin 3 \tag{7.18}$$

1.H13

For every pair of upper voices, the thesis note of each measure must never form a minor second interval.
This rule is applied to every species of counterpoint in three and four voices configuration.

$$\begin{gathered} \forall j \in [0, m-1], \quad s_1, s_2 \in \{b, c, d\} \\ H(s_1, s_2)[0, j] \neq 1 \end{gathered} \tag{7.19}$$

Melodic Rules

1.M2

Intervals cannot exceed a minor sixth interval, but octave leaps are allowed in three and four voices
This rule applies to all first-species counterpoints.

`2V:`

$$\begin{gathered} \forall j \in [0, m-2] \\ M[0, j] \leq 8 \end{gathered} \tag{7.20}$$

`3V & 4V:`

$$\begin{gathered} \forall j \in [0, m-2] \\ \big(M[0, j] \leq 8 \ \vee \ M[0, j] = 12\big). \end{gathered} \tag{7.21}$$

1.M4

The notes of each part should be as diverse as possible.
This rule applies to all configurations in three and four voices.

$$\begin{gathered} \forall p \in \{cp1, cp2, cp3\}, \ \forall j \in [0, m-1], \ \forall k \in [j+1, \min(j+3, m-1)] : \\ \big(N(p)[0, j] = N(p)[0, j * k]\big) \iff C_{variety}[j + m \cdot k] = 2. \end{gathered} \tag{7.22}$$

Motion Rules

1.P1 & 3.P2

Reaching a perfect consonance by direct motion is forbidden in two voices, and should be avoided when composing for three and four voices. In four voice composition, it is to be tolerated between inner voices rather than outer voices.
This rule applies to all configurations.

2V:

$$\begin{gathered}\forall j \in [0, m-2] \\ H[0, j+1] \in Consp \;\Rightarrow\; P[0, j] \neq 2\end{gathered} \tag{7.23}$$

3V:

$$\begin{gathered}\forall j \in [0, m-2] \\ \big(P[0, j] = 2 \wedge H[0, j+1] \in Cons_p\big) \iff C_{direct\_move\_to\_p\_cons}[j] = 8\end{gathered} \tag{7.24}$$

4V:

$$\begin{aligned}&P(b)[0, j] = 2 \wedge H(b)[0, j] \in Cons_p \wedge H(b)[0, j+1] \in Cons_p \iff C_{direct\_move\_to\_p\_cons}[j] = 2,\\ &P(c)[0, j] = 2 \wedge H(c)[0, j] \in Cons_p \wedge H(c)[0, j+1] \in Cons_p \iff C_{direct\_move\_to\_p\_cons}[j] = 2,\\ &P(d)[0, j] = 2 \wedge H(d)[0, j] \in Cons_p \wedge H(d)[0, j+1] \in Cons_p \iff C_{direct\_move\_to\_p\_cons}[j] = 8.\end{aligned} \tag{7.25}$$

1.P2

Contrary motions are preferred to oblique motions which are preferred to direct motions.
This rule applies in all configurations.

$$\begin{gathered}\text{With } cost_{con} = 0 \quad \text{and} \quad cost_{con} < cost_{obl} < cost_{dir} \\ \forall j \in [0, m-1] \\ P_{costs}[j] = \begin{cases} cost_{con} & \text{if } P[0, j] = 0, \\ cost_{obl} & \text{if } P[0, j] = 1, \\ cost_{dir} & \text{if } P[0, j] = 2. \end{cases}\end{gathered} \tag{7.26}$$

1.P3

At the start of any measure, an octave cannot be reached by the lower voice going up and the upper voice going down more than a third skip.
This rule applies in all configurations.

$$\begin{gathered}i := \max(B),\ \forall j \in [0, m-1],\ \forall p \in \{cf, cp1, cp2, cp3\} \\ H(p)[0, j+1] = 0 \wedge P(p)[i, j] = 0 \wedge M_{brut}(p)[i, j] < -4 \wedge \neg A(p) \iff \bot,\end{gathered} \tag{7.27}$$

1.P4

Successive perfect consonances should be avoided.
This rule applies in all configurations, except second species in three and four voices (see 2.P3).

$$\begin{gathered}\forall p_1 \neq p_2 \in \{cf, cp1, cp2, cp3\},\ \forall j \in [0, m-1] \\ \big(H(p_1,p_2)[0,j] \in Cons_p \wedge H(p_1,p_2)[0,j+1] \in Cons_p\big)\ \Rightarrow\ C_{succ\_p\_cons} = 2.\end{gathered} \tag{7.28}$$

1.P5

Each part starts distant from the lowest stratum.

This is a general indication for the composer (to make it easier for parts to move towards each other in contrary motion), but no explicit constraint is implemented.

1.P6

It is prohibited that all parts move in the same direction.
This rule applies in three and four voices configurations.

$$\begin{gathered}\forall j \in [0, m-1] \\ \bigvee_{p \in \{cf, cp1, cp2, cp3\}} P(p)[0,j] \in \{0,1\}.\end{gathered} \tag{7.29}$$

1.P7

It is prohibited to use successive ascending sixths on a direct upwards motion.
This rule applies to all configurations in three or four voices.

$$\begin{gathered}\forall j \in [1, m-1],\ \forall p_1 \neq p_2,\ \text{with } sixth := \{8, 9\} \\ H(p_1,p_2)[0,j-1] \notin sixth \\ \vee\ H(p_1,p_2)[0,j] \notin sixth \\ \vee\ M_{brut}(p_1)[0,j] \leq 0 \\ \vee\ M_{brut}(p_2)[0,j] \leq 0\end{gathered} \tag{7.30}$$

7.3 Constraints of the Second Species

Harmonic Rules

2.H2

Arsis harmonies cannot be dissonant except if there is a diminution[1].
This rule applies to all numbers of voices, on second species counterpoints.

$$\forall j \in [0, m-2],\ \forall p:\ species(p) = 2$$

$$IsDim(p)[j] = \begin{cases} \top & \text{if } M^2(p)[0,j] \in \{3,4\} \wedge M^1(p)[0,j] \in \{1,2\} \wedge M^1(p)[2,j] \in \{1,2\} \\ \bot & \text{otherwise} \end{cases}$$

$$\forall j \in [0, m-2] \quad \neg IsCons(p)[2,j] \ \Rightarrow\ IsDim(p)[j] \tag{7.31}$$

2.H3 & 2.H4

When composing in two voices, in the penultimate measure the harmonic interval of perfect fifth must be used for the thesis note if possible. Otherwise, a sixth interval should be used instead.
This rule applies to all two voice configurations in which the counterpoint is of the second species.

$$H[0, m-2] \in \{7, 8, 9\}$$

$$penulthesiscost = \begin{cases} cost_{penulthesis} & \text{if } H[0,m-2] \neq 7 \\ 0 & \text{otherwise} \end{cases} \tag{7.32}$$

2.H6 & 3.H5

The half notes (or quarter notes in the third species) must be coherent ("concordant") with respect to the whole notes.

This is not really a constraint, but more of an indication. It was decided to leave it in this complete set of rules because it is a redundant concept in *Gradus ad Parnassum*.

[1] Remember that a diminution consists of an intermediate note that exists between two notes separated by a skip of a third.

Melodic Rules

2.M1

If the two voices are getting so close that there is no contrary motion possible without crossing each other, then the melodic interval of the counterpoint can be an octave leap.
This rule applies to all two voice configurations in which the counterpoint is of the second species.

$$\begin{gathered} \forall j \in [0, m-2],\ \forall M_{cf}[j] \neq 0 \\ M[0,j] = 12 \ \Rightarrow\ (H[0,j] \leq 4) \ \wedge\ (\neg A(cp)[j] \ \Leftrightarrow\ M_{cf}[j] > 0) \end{gathered} \tag{7.33}$$

2.M2

In two-voice composition, two consecutive notes cannot be the same. When writing a three or four voice composition, the 4th-to-last, the 3rd-to-last and the 2nd-to-last may be the same.
This rule applies to all configurations, to second species counterpoints.

`2V:`

$$\begin{gathered} \forall \rho \in \mathit{positions}(m) \\ N[\rho] \neq N[\rho+1] \end{gathered} \tag{7.34}$$

`3V & 4V:`

$$\begin{gathered} \forall p:\ \mathit{species}(p) = 2,\ \forall j \in [1, m-3] \\ \big((N[2,j-1] \neq N[0,j]) \wedge (N[0,j] \neq N[2,j])\big) \ \wedge \\ \big((N[2,m-3] \neq N[0,m-2]) \vee (N[0,m-2] \neq N[2,m-2])\big) \end{gathered} \tag{7.35}$$

Motion Rules

2.P1 & 1.P2

If the melodic interval of the counterpoint between the thesis and the arsis is larger than a third, then the motion is perceived based on the arsis note.
This rule applies to all counterpoints of the second species.

$$\begin{gathered} \forall j \in [0, m-2] \\ \mathit{Preal}[j] = \begin{cases} P[2,j] & \text{if } M[0,j] > 4 \\ P[0,j] & \text{otherwise} \end{cases} \end{gathered} \tag{7.36}$$

Note: The rule concerning the battuta octave (1.P3) always perceives motion from the last note of the previous measure, but this is already explicitly for-

mulated in the formalization of the rule, so it does not impact this rule or need a new formulation.

2.P3

For three and four part composition, successive fifths on the downbeat are only allowed when they are separated by a third on the upbeat.
This rule applies to all configurations in three and four voice composition in which second species counterpoints are involved.

$$\forall p_1, p_2 \in \{cf, cp1, cp2, cp3\} \text{ with } p_1 \neq p_2 \text{ and } (species(p_1) = 2 \vee species(p_2) = 2), \quad \forall j \in [0, m-3]$$

$$Cost_{succ\_p\_cons} = \begin{cases} 0 & \text{if } (H(p_1,p_2)[0,j] \notin Cons_p) \ \vee \ (H(p_1,p_2)[0,j+1] \notin Cons_p) \\ 0 & \text{if } (H(p_1,p_2)[0,j] = 5) \ \wedge \ (H(p_1,p_2)[0,j+1] = 5) \\ & \quad \wedge \big(H(p_1,p_2)[2,j] \in \{3,4\}\big) \\ 2 & \text{otherwise} \end{cases} \tag{7.37}$$

7.4 Constraints of the Third Species

Harmonic Rules

3.H1

If five notes follow each other by joint degrees in the same direction, then the harmonic interval of the third note must be consonant.
This rule applies in all configurations, to third species counterpoints.

As discussed in section 6.3, this rule is currently disabled and must be modified in a future work.

3.H2

If the third harmonic interval of a measure is dissonant then the second and the fourth interval must be consonant and the third note must be a diminution.

$$\forall j \in [0, m-3]$$
$$IsCons[2,j] \vee (IsCons[1,j] \wedge IsCons[3,j] \wedge IsDim[j])$$
where $IsDim[j] = \top$ when the 3^{rd} note of the measure j is a dimension. (7.38)

3.H3

It is best to avoid the second and third harmonies of a measure to be consonant with a one-degree melodic interval between them.
This rule applies in all configurations, to third species counterpoints.

$$\forall j \in [0, m-2]$$
$$Cambiatacosts[j] = \begin{cases} cost_{Cambiata} & \text{if } IsCons[1,j] \wedge IsCons[2,j] \wedge M[1,j] \leq 2 \\ 0 & \text{otherwise} \end{cases} \tag{7.39}$$

3.H4

In two voice composition, in the penultimate measure, if the counterpoint is the lowest stratum, then the harmonic interval of the first note should be a minor third.

$$A(cp)[m-2] \implies H[0, m-2] = 3 \tag{7.40}$$

3.H6

If the harmonic triad could not be used on the downbeat, it should be used on the second or third beat.
This rule applies in all three and four voice configurations in which there is a third species counterpoint.

$$\forall j \in [0, m-2]$$
$$(H[0,j] \notin Cons_{h\_triad}) \wedge (H[1,j] \notin Cons_{h\_triad}) \wedge (H[2,j] \notin Cons_{h\_triad})$$
$$\iff cost_{harmonic\_triad\_3rd\_species}[j] = 1 \tag{7.41}$$

3.H7

On the downbeat of a four-part composition, it is now preferred to double the third or the fifth, rather than to use a unison.
This rule applies only in four voice composition, when a third species counterpoint is involved.

This rule is handled by 1.H8 by setting *triad_with_unison_cost* superior to the *double_thirds_cost* and the $double\_fifths\_cost$.

Melodic Rules

3.M1

Each note and its two beats further peer are preferred to be different.
This rule applies in all configurations, to third species counterpoints.

$$\begin{gathered}\forall \rho \in positions(m-2) \\ MtwoSame_{costs}[i,j] = \begin{cases} cost_{MtwoSame} & \text{if } M^2[\rho] = 0 \\ 0 & \text{otherwise} \end{cases}\end{gathered} \tag{7.42}$$

3.M2

No melodic interval between 9 and 11 semitones.
This rule applies to all third-species counterpoints.

$$\begin{gathered}\forall i \in \mathcal{B}, \quad \forall j \in [0, m-2], \\ M[i,j] \notin \{9, 10, 11\}\end{gathered} \tag{7.43}$$

3.M3

The second note of the penultimate measure must be more than a semitone away from the fourth note.
This rule applies to all third-species counterpoints.

$$M_{brut}[1, m-2] + M_{brut}[2, m-2] > 1 \tag{7.44}$$

Motion Rules

3.P1

The motion is perceived based on the fourth note.
This rule applies in all configurations, to third species counterpoints.

$$\begin{gathered}\forall j \in [0, m-2] \\ P_{real}[j] = P[3, j]\end{gathered} \tag{7.45}$$

7.5 Constraints of the Fourth Species

Harmonic Rules

4.H1

Arsis harmonies must be consonant.
This rule applies in all configurations, to fourth species counterpoints.

$$\begin{array}{c} \forall j \in [0, m-2] \\ H[2, j] \in Cons \end{array} \tag{7.46}$$

4.H2

In two part composition, if the fourth species counterpoint is the lowest stratum, then no harmonic seventh interval can occur.
This rule applies to two voice compositions in which the counterpoint is of the fourth species.

$$\begin{array}{c} \forall j \in [1, m-2] \\ A(cp)[j] \;\Rightarrow\; H[0, j] \notin \{10, 11\} \end{array} \tag{7.47}$$

4.H3

In the penultimate measure, the harmonic interval of the thesis note must be a major sixth or a minor or major third depending on the cantus firmus pitch.
This rule applies to two voice compositions in which the counterpoint is of the fourth species.

$$H[0, m-2] = \begin{cases} 9 & \text{if } A(cf)[m-2] \\ 3 \vee 4 & \text{otherwise} \end{cases} \tag{7.48}$$

Melodic Rules

4.M1

Arsis half notes should be the same as their next halves in thesis.
This rule applies in all configurations, to fourth species counterpoints.

$$\begin{array}{c} \forall j \in [0, m-2] \\ NoSync_{costs} = \begin{cases} cost_{NoSync} & \text{if } M[2, j] \neq 0 \\ 0 & \text{otherwise} \end{cases} \end{array} \tag{7.49}$$

The cost should be set high, because this syncopation is the very nature of the species.

4.M2

Each arsis note and its two measures further peer are preferred to be different.
This rule applies in all configurations, to fourth species counterpoints.

$$\forall j \in [0, m-2]$$
$$MtwomSame_{costs} = \begin{cases} cost_{MtwomSame} & \text{if } N[2,j] = N[2,j+2] \\ 0 & \text{otherwise} \end{cases} \tag{7.50}$$

Motion Rules

4.P1

Dissonant harmonies must be followed by the next lower consonant harmony.
This rule applies in all configurations, to fourth and fifth species counterpoints.

`4sp:`

$$\begin{gathered} \forall j \in [1, m-1] \\ \neg isCons[0,j] \implies M_{brut}[0,j] \in \{1,2\} \end{gathered} \tag{7.51}$$

`5sp:`

$$\begin{gathered} \forall j \in [1, m-1] \\ \neg isCons[0,j] \wedge S[0,j] = 4 \implies M^2_{brut}[0,j] \in \{1,2\} \end{gathered} \tag{7.52}$$

The use of M^2 is justified because, in the fifth species, every beat can potentially contain a note. In this case, it is necessary to check the melodic interval specifically between the thesis and the arsis note.

4.P2

If the fourth species counterpoint is not the lowest stratum then no second harmony can be preceded by a unison/octave harmony.
This rule applies in all configurations, to fourth species counterpoints.

$$\begin{gathered} \forall j \in [1, m-2] \\ \neg A[j+1] \;\Rightarrow\; H[2,j] \neq 0 \;\wedge\; H[0,j+1] \notin \{1,2\} \end{gathered} \tag{7.53}$$

7.6 Constraints of the Fifth Species

Melodic Rules

5.M1

No unison between two consecutive notes.
This rule applies to all fifth species counterpoints.

$$\begin{gathered}\forall j \in [0, m-2], \\ N[0,j] \neq N[1,j], \\ N[1,j] \neq N[2,j], \\ N[2,j] \neq N[3,j] \\ N[3,j] \neq N[0,j+1]\end{gathered} \tag{7.54}$$

5.M2

For each measure from the second to the second-to-last, if a note is part of the fourth species and the corresponding subsequent note is constrained, then these two notes must not be the same.
This rule applies to all fifth species counterpoints.

$$\begin{gathered}\forall j \in [1, m-2] \\ (S[0,j] = 4 \wedge S[2,j] = 4) \implies N[0,j] \neq N[2,j]\end{gathered} \tag{7.55}$$

Rhythmic Rules

The fifth species does not operate in the same manner as the previous four. In this case, the S array is used to indicate the species assigned to each note, describing both its rhythmic value and the rules that govern it. The rhythmic constraints outlined below are defined on this S array, and from it one can deduce, via the equations of this section, which set of rules applies to every note.

To make the formalization more readable, we define $IsSx$:

$$\begin{gathered}\forall x \in \{0,1,2,3,4\},\ \forall \rho \in positions(m) \\ IsSx[\rho] = \begin{cases} \top & \text{if } S[\rho] = x \\ \bot & \text{otherwise} \end{cases}\end{gathered} \tag{7.56}$$

5.R1

There must always be a note in thesis and in arsis, except the very first thesis and the very last arsis.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered}\forall j \in [0, m-1] \\ \neg IsS_0[0,j] \quad \text{where } j \neq 0\end{gathered} \tag{7.57}$$

$$\forall j \in [0, m-1]: \quad \neg IsS_0[2,j] \quad \text{where } j \neq m-1 \tag{7.58}$$

5.R2

The 4th species can only exist in first and third beat.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered}\forall i \in \{1,3\},\ \forall j \in [0, m-1] \\ \neg IsS_4[i,j]\end{gathered} \tag{7.59}$$

5.R3

A 4th species in the third beat necessarily implies a 4th species in the first beat of the following measure and vice versa. The fourth beat should then have no note.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered}\forall j \in [0, m-2] \\ IsS_4[2,j] \iff IsS_4[0,j+1]\end{gathered} \tag{7.60}$$

$$\begin{gathered}\forall j \in [0, m-2] \\ IsS_4[2,j] \implies IsS_0[3,j]\end{gathered} \tag{7.61}$$

5.R4

A 3rd species cannot be followed by no note.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered}\forall \rho \in positions(m-1) \\ IsS_3[\rho] \implies \neg IsS_0[\rho+1]\end{gathered} \tag{7.62}$$

5.R5

Only 3rd species and 4th species are used.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered}\forall \rho \in positions(m) \\ \neg IsS_1[\rho] \ \wedge \ \neg IsS_2[\rho]\end{gathered} \tag{7.63}$$

5.R6

The first and penultimate measures are linked to the 4th species.
This rule applies in all configurations, to fifth species counterpoints.

$$IsS_0[0,0] \wedge IsS_0[1,0] \wedge IsS_4[2,0] \tag{7.64}$$

$$IsS_4[0, m-2] \wedge IsS_0[1, m-2] \wedge IsS_4[2, m-2] \tag{7.65}$$

5.R7

An arsis note, regardless of its species, must be the consonance just below the thesis note if the latter belongs to the fourth species.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered} \forall j \in [1, m-2] \\ \neg IsCons[0, j] \wedge IsS_4[0, j] \implies M^2_{brut}[0, j] \in \{-1, -2\} \wedge IsCons[2, j] \end{gathered} \tag{7.66}$$

5.R8

To avoid multiple same final solutions, the non-displayed notes (whose values in S are 0) must be of the same value as the note on the next beat.
This rule applies in all configurations, to fifth species counterpoints.

$$\begin{gathered} \forall \rho \in positions(m-1) \\ IsS_0[\rho] \implies (N[\rho] = N[\rho + 1]) \end{gathered} \tag{7.67}$$

5.R9

When composing two counterpoints of the fifth species, the counterpoints must use different species for at least half of the beats. If there are three counterpoints of the fifth species, this rule applies between the fifth species counterpoint with the minimum range and the one with the maximum range. The middle one remains unconstrained by this rule.
This rule applies when there are multiple counterpoints of the fifth species.

$$species(cp_1) = species(cp_2) = 5 \iff \sum_{i=0}^{3} \sum_{j=0}^{m-1} (S(cp_1)[i, j] = S(cp_2)[i, j]) < \frac{sm}{2} \tag{7.68}$$

Determining the Constraints that Apply to Each Note

$$\begin{gathered} \forall x \in \{3, 4\},\ \forall cst_x \in Constraints(x),\ \forall V \in Variables(cst_x) \\ \Big(\bigwedge_{v \in V} IsS_x[v_{pos}] \Big) \implies cst_x(V) \end{gathered} \tag{7.69}$$

where $Constraints(x)$ is the set of constraints of the species x, and $Variables(cst_x)$ is the set of variables concerned by the constraint cst_x, and v_{pos} is the position of the v related note in the array N.

Special case for 1.H1 and 4.H1

$$\forall j \in [0, m-1]: \quad IsS_3[0,j] \implies (H[0,j] \in Cons) \tag{7.70}$$

$$\begin{gathered} \forall j \in [0, m-2] \\ IsS_4[2,j] \implies (H[2,j] \in Cons) \end{gathered} \tag{7.71}$$

7.7 Tables of rules scope

	All species	**First sp.**	**Second sp.**	**Third sp.**	**Fourth sp.**	**Fifth sp.**

Table 7.1: Table of Scopes

Chapter 8

Limitations and Future Work

This work consolidates and validates a significant part of the Fux counterpoint model, highlighting areas where the implementation and formal rule set fall short of current practice. Below, I summarise the main limitations encountered during the project and outline concrete next steps that remain faithful to Fux while leveraging the clarity of Gallon–Bitsch.

8.1 Limitations

Code readability and duplicated logic

A very practical obstacle was the codebase itself. Many files lack comments or brief rationales at the point where constraints are posted. Combined with this, each species counterpoint class often maintains its own interval arrays—sometimes several—with different sizes and even different implementations. In practice this makes it hard to know which array is "the" authoritative one to use when debugging or extending a rule. This duplication also clashes with the conceptual unification already present in the model through the core arrays N, H, M, P and the species grid S, and with the shared class structure described earlier.

Feature gaps surfaced by figure-driven validation

When I validated the solver against Fux's figures using MUS, I had to adapt many fifth-species examples: the current program does not yet cover several fifth-species rhythms and ornaments. In effect, I restricted fifth species to quarter notes (third species behaviour) and tied half notes (fourth species syncopations) to make the tests executable. This means the solver cannot yet reproduce Fux's florid variety verbatim.

Relatedly, certain tolerances documented during the audit are not encoded yet. Examples include the use of a second-species syncopation in the penultimate bar, which I had to test without syncopation because it is not currently

supported, and cadential tolerances (e.g., the diminished fifth in the penultimate bar when the bass delays the leading tone) that appear in the literature but are not fully parameterized in the solver.

Incomplete rule coverage across contexts

Some rules required by analysis are disabled or only partially applied across species/voice counts due to where they are posted in the class hierarchy (e.g., implementation tied to a specific species constructor instead of the voice-configuration layer). This surfaced during MUS analysis and refactoring plans (e.g., for penultimate-bar cadence rules).

Test coverage imbalance

I began with unit tests but only implemented about ten constraint-level tests before switching to figure-driven MUS diagnostics, which proved far more informative for real examples. As a result, low-level unit coverage remains thin.

Limited interactivity/integration at this stage

The implementation is now a standalone C++ library (the OpenMusic dependency is gone), and a native C++ UI is being developed separately. Until that UI work lands, day-to-day composition workflows remain code-centric and less interactive than desired.

8.2 Future Work

Bring in Gallon–Bitsch—explicitly, but keep Fux the default

A clear, high-leverage next step is to encode the rules from Noël Gallon & Marcel Bitsch. Their treatise is numbered, explicit, and exhaustive, which maps naturally to constraints and helps resolve remaining ambiguities. I want to use it as a clarifying layer while preserving Fux style as the goal and default—i.e., provide a "Gallon–Bitsch profile" that can be toggled or intersected with Fux, not a replacement. The thesis already uses Gallon–Bitsch as an authoritative cross-check; formalizing those rules directly will make the solver clearer, more complete, and easier to extend—without drifting from Fux.

Refactor to a single "theory kernel"

To eliminate confusion and duplication:

- **Centralize interval/motion helpers** (harmonic, melodic, motion categories) into one shared module parameterized by species and voice count.
- **Retire per-species interval arrays** (with divergent sizes/implementations) in favour of a single authoritative representation that all species use.

- **Add lightweight comments** where constraints are posted: what rule (and source) is being encoded, scope (species/voices), and any tolerated exceptions.

This aligns the code with the already unified conceptual arrays N, H, M, P, S and the class hierarchy documented earlier.

Complete missing behaviours exposed by validation

- **Fifth species:** implement the absent rhythmic figures/ornaments so Fux's florid examples can run without simplification. At least allowed the use of first and second species type note in fifth species part.
- **Second-species penultimate syncopation:** add the allowed syncopated cadence option used in the sources.
- **Cadential tolerances:** encode the documented, tightly scoped tolerances (e.g., diminished fifth with delayed leading tone in the bass) behind explicit switches.
- **Constructor placement of global rules:** move cadence rules that must hold across species (e.g., penultimate-bar intervals) to the voice-configuration layer so they're always active in the right contexts.

Strengthen tests without losing MUS benefits

Keep MUS for figure-level diagnosis, and complement it with:

- **Property-style unit tests** for low-level helpers (interval reductions, motion detection, stratum mapping).
- **Rule-scope smoke tests** per species/voice count to catch constructor-scope regressions early.

Integrate the upcoming UI

Once the native C++ UI is available, expose:

- **Constraint toggles and profiles** (Fux vs. Gallon–Bitsch) and
- **MUS-based explanations** ("which minimal rule set broke this edit?")

so users can lock notes, make local edits, and re-solve with immediate feedback.

Chapter 9

Conclusion

This thesis set out to turn the pedagogy of species counterpoint into an explicit, testable computational model: a clarified rule system faithful to Fux, implemented over a constraint solver, and validated by systematic tests. In doing so, it connects three strata that are often kept apart—historical sources, a formal theory, and working software—so that each can inform and check the others.

9.1 What was delivered

Conceptually, the work consolidates and corrects the formal model of Fuxian counterpoint, distinguishing necessities (hard rules) from tendencies (soft preferences) and using Minimal Unsatisfiable Subsets (MUS) to pinpoint tensions between the specification and canonical examples. Practically, it extends and fixes the Gecode-based implementation, adds a modular on/off mechanism for constraints, integrates MUS diagnostics into the testing loop, and unifies the rule library and its documentation into a reproducible framework. The core arrays N, H, M, P and the species grid S provide a common vocabulary to express melodic, harmonic and rhythmic structure in a way that is both human-legible and solver-friendly.

The project also completes an engineering transition begun in prior work: FuxCP no longer depends on OpenMusic and is maintained as a standalone C++ library on Gecode, with a native C++ UI being developed separately. This decoupling preserves transparency and makes broader integration easier.

9.2 What we learned

Figure-driven MUS analysis proved decisive. In practice, every failing example was explained by a single constraint—MUS sets never exceeded size one—supporting the model's modularity and making fixes tractable. At the same time, several fifth-species figures had to be simplified because some rhythmic patterns and ornaments are not yet handled; restricted tests used third-

species quarters and fourth-species ties for syncopation. During diagnostics, previously undocumented rules surfaced in code and were tracked explicitly. Finally, the audit highlighted duplicated interval/motion tables scattered across species classes—an obstacle to clarity and extension.

9.3 Why it matters

Constraint Programming remains a fitting foundation: rules are explicit and traceable; preferences encode stylistic latitude; and solutions are inspectable rather than opaque. In context, FuxCP is designed to assist composition and is positioned for pedagogical use—provided the solver's explanations and interfaces continue to mature.

9.4 Where this naturally goes next

With the Fux corpus now reviewed and corrected where needed, the next tractable step is to encode the numbered, explicit rules of Noël Gallon and Marcel Bitsch as an auxiliary source—resolving ambiguities while preserving a Fux-first "style profile." In parallel, a refactor to a single "theory kernel" (one authoritative set of interval/lookup utilities shared by all species/voice counts) should eliminate duplication and lower cognitive load. Completing missing fifth-species behaviours, targeting mixed-species textures such as the four-voice *grand mélange*, and integrating the forthcoming UI with explainable feedback and standard I/O (MusicXML/MIDI) round out the roadmap, alongside empirical classroom studies.

9.5 Closing

The combined outcome is a clearer, more faithful executable reading of species counterpoint: a validated catalogue of rules, an implementation that explains its own failures, and a workflow that reproduces canonical figures where supported and identifies precisely where the model must evolve. These foundations make the next extensions—Gallon–Bitsch, cleaner internals, richer rhythms, and denser textures—both feasible and well-motivated.

Author's Note on Language Assistance

All ideas, structure, and academic argumentation in this thesis—including the formulation of the research questions, the design of the methods, the analysis of the results, and the final interpretations—are entirely my own. To improve clarity, fluency, and grammar in English, I used ChatGPT as an editing aid for phrasing and style. The tool did not generate new content, nor did it determine the substance of the work. Responsibility for all content and any remaining errors is mine alone.

Appendix A

Complete FuxCP Code

It is required to include all of the code of FuxCP in the appendix of master thesis. Everything is available on GitHub (https://github.com/TomLaiUCL/FuxCP5). This appendix serves to leave an additional trace of the code.
